GAMA 1.8 - GAML Quick Reference for Beginners

Srirama Bhamidipati

Updated: 2019-05-09 11:15:47 (Amsterdam)

Contents

Foreword

- The main purpose of this book is to provide a simple introduction with bare minimum content that helps the reader to get started with GAMA Language (GAML).

- The content of this manual is from gama-platform.org website. I have modified and edited portions of the content to give a cleaner format.

- This is a modified content and is not a 100% reproduction. If you do not find what you are looking for, go to the main website.

- See downloads section for a different way to obtain full GAMA documentation.

- I thank the Team of GAMA-Platform for giving me the permission to reproduce their content.

Cheers !

Editions

- Corrections: 7th May 2019, Hanoi
- **Second Edition**: 19 January 2019
- Syntax Highlighting (pdf)
- Formatted code (pdf)
- **First Edition**: June 2018
- b/w code (pdf)
- Unformated code (pdf)

Report Errors/ Give Feedback

If you find any problems/typos/errors related to this book, you can report issues on this page. On this page you can click the big green button "New Issue" and fill in the details. Typically, you should fill

- name of the book
- a link to the book
- page or section number that has the error

You can also leave a feedback on the same page, just select the label for "feedback".

Downloads

- Software

- You can download the **stable release** from: https://github.com/gama-platform/gama/releases/tag/oxygen

- Or you can download the **nightly build** from: https://github.com/gama-platform/gama/releases/tag/latest

- Full Documentation for offline viewing

- You can use free professional docset viewers like Kapeli Dash, Velocity and Zeal **docset viewers** to view GAMA documentation

- To do so, download this zip file, unzip, and add it as a local docset from Options/ Preferences / Settings of these viewers.

- Download Docset

Chapter 1

Java version

Due to changes in the libraries used by GAMA 1.7 and 1.8, this version now **requires JDK/JVM 1.8** to run. Please note that GAMA **has not been tested with JDK 1.9 and 1.10**.

1.1 Changes between 1.6.1 and 1.7/1.8 that can influence the dynamics of models

- Initialization order between the initialization of variables and the execution of the `init` block in grids init -> vars in 1.6.1 / vars -> init in 1.7
- Initialization order of agents -> now, the init block of the agents are not executed at the end of the global init, but during it. put a sample model to explain the order of creation and its differences
- Initialization of vars to their default value map ? list ?
- Systematic casting and verification of types give examples
- header of CSV files: be careful, in GAMA 1.7, if the first line is detected as a header, it is not read when the file is casted as a matrix (so the first row of the matrix is not the header, but the first line of data) gives examples
- the step of batch experiments is now executed after all repetitions of simulations are done (not after each one). They can however be still accessed using the attributes `simulations` (see Batch.gaml in Models Library)
- signal and diffuse have been merged into a single statement
- facets do not accept a space between their identifier and the : anymore.
- simplification of equation/solve statements and deprecation of old facets
- in FIPA skill, `content` is replaced everywhere with `contents`
- in FIPA skill, `receivers` is replaced everywhere with `to`
- in FIPA skill, `messages` is replaced by `mailbox`
- The pseudo-attribute `user_location` has been removed (not deprecated, unfortunately) and replaced by the "unit" `#user_location`.
- The actions called by an `event` layer do not need anymore to define `point` and `list<agent>` arguments to receive the mouse location and the list of agents selected. Instead, they can now use `#user_location` and they have to compute the selected agents by themselves (using an arbitrary function).
- The random number generators now better handle seeding (larger range), but it can change the series of values previously obtained from a given seed in 1.6.1
- all models now have a starting_date and a current_date. They then dont begin at an hypothetical "zero" date, but at the epoch date defined by ISO 8601 (1970/1/1). It should not change models that dont rely on dates, except that:
- the #year (and its nicknames #y, #years) and #month (and its nickname #month) do not longer have a default value (of resp. 30 days and 360 days). Instead, they are always evaluated against the

current_date of the model. If no starting_date is defined, the values of #month and #year will then depend on the sequence of months and year since epoch day.

- `as_time`, `as_system_time`, `as_date` and `as_system_date` have been removed

Chapter 2

Enhancements in 1.7/1.8

2.1   Simulations

- simulations can now be run in parallel withing an experiment (with their outputs, displays, etc.)
- batch experiments inherit from this possibility and can now run their repetitions in parallel too.
- concurrency between agents is now possible and can be controlled on a species/grid/ask basis (from multi-threaded concurrency to complete parallelism within a species/grid or between the targets of an `ask` statement)

2.2   Language

- `gama` : a new immutable agent that can be invoked to change preferences or access to platform-only properties (like `machine-time`)
- `abort`: a new behavior (like `reflex` or `init`) that is executed once when the agent is about to die
- `try` and `catch` statements now provide a robust way to catch errors happening in the simulations.
- `super` (instead of `self`) and `invoke` (instead of `do`) can now be used to call an action defined in a parent species.
- `date` : new data type that offers the possibility to use a real calendar, to define a `starting_date` and to query a `current_date` from a simulation, to parse dates from date files or to output them in custom formats. Dates can be added, subtracted, compared. Various new operators (`minus_months`, etc.) allow for a fine manipulation of their data. Time units (`#sec`, `#s`, `#mn`, `#minute`, `#h`, `#hour`, `#day`, etc.) can be used in conjunction with them. Interval of dates (date1 to date2) can be created and used as a basis for loops, etc. Various simple operators allow for defining conditions based on the current_date (after(date1), before(date2), since(date1), etc.).
- `font` type allows to define fonts more precisely in `draw` statements
- BDI control architecture for agents
- file management, new operators, new statements, new skills(?), new built-in variables, files can now download their contents from the web by using standard http: https: addresses instead of file paths.
- The `save` can now directly manipulate files and … save them. So something like `save shape_file("bb.shp", my_agents collect each.shape);` is possible. In addition, a new facet `attributes` allows to define complex attributes to be saved.
- `assert` has a simpler syntax and can be used in any behaviour to raise an error if a condition is not met.
- `test` is a new type of experiments (`experiment aaa type: test ...`), equivalent to a `batch` with an exhaustive search method, which automatically displays the status of tests found in the model.
- new operators (`sum_of`, `product_of`, etc.)

15

- casting of files works
- co-modeling (importation of micro-models that can be managed within a macro-model)
- populations of agents can now be easily exported to CSV files using the `save` statement
- Simple `messaging` skill between agents

- Terminal commands can now be issued from within GAMA using the `console` operator
- New `status` statement allows to change the text of the status.
- light statement in 3D display provides the possibility to custom your lights (point lights, direction lights, spot lights)
- Displays can now inherit from other displays (facets `parent` and `virtual` to describe abstract displays)
- `on_change:` facet for attributes/parameters allows to define a sequence of statements to run whenever the value changes.
- `species` and `experiment` now support the `virtual` boolean facet (virtual species can not be instantiated, and virtual experiments do not show up).
- `experiment` now supports the `auto_run` boolean facet (to run automatically when launched)
- `experiment` now supports the `benchmark` boolean facet (to produce a CSV summary of the time spent in the different statements / operators of GAMA)
- experiments can now have their own file (`xxx.experiment`) and specify the model they are targeting by providing the path to the model in the new `model:` facet (similar to `import`).
- experiments can sport a new type: `test`, a specialised type of batch experiment that can be run automatically from the GUI or in headless and reports back the result of the tests found in its model

2.3   Data importation

- draw of complex shapes through obj file
- new types fo files are taken into account: geotiff and dxf
- viewers for common files
- addition of plugin and test models

2.4   Navigator

- Shapefiles are now copied, pasted and deleted together with their support files
- External files are automatically linked from the workspace and the links are filed under an automatically created `external` folder in the project
- The "Refresh" command in the navigator pop-up refreshes the files, cleans the metadata and recompiles the models in order to obtain a "fresh" workspace again
- A search control allows to instantaneously find models based on their names (not contents)
- Wizards for creating `.experiment` file and test experiments
- The new project Wizard now leads by default to the new file wizard

2.5   Editor

- doc on built-in elements, templates, shortcuts to common tasks, hyperlinks to files used
- improvement in time, gathering of infos/todos
- warnings can be removed from model files
- resources / files can be dropped into editors to obtain declaration/import of the corresponding files

2.6 Headless

- A new option `-validate path/to/dir` allows to run a complete validation of all the models in the directory
- A new option `-test path/to/dir` allows to run all the tests defined in a directory

2.7 Models library:

- New models (make a list)

2.8 Preferences

- For performances and bug fixes in displays
- For charts defaults

2.9 Simulation displays

- OpenGL displays should be up to 3 times faster in rendering
- fullscreen mode for displays (ESC key)
- CTRL+O for overlay and CTRL+L for layers side controls
- cleaner OpenGL displays (less garbage, better drawing of lines, rotation helper, sticky ROI, etc.)
- possibility to use a new OpenGl pipeline and to define keystoning parameters (for projections)
- faster java2D displays (esp. on zoom)
- better user interaction (mouse move, hover, key listener)
- a whole new set of charts
- getting values when moving the mouse on charts
- possibility to declare `permanent layout:` + `#splitted`, `#horizontal`, `#vertical`, `#stacked` in the `output` section to automatically layout the display view.
- Outputs can now be managed from the "Views" menu. Closed outputs can be reopened.
- Changing simulation names is reflected in their display titles (and it can be dynamic)
- OpenGL displays now handle rotations of 2D and 3D shapes, combinations of textures and colours, and keystoning

2.10 Error view

- Much faster (up to 100x !) display of errors
- Contextual menu to copy the text of errors to clipboard or open the editor on it

2.11 Validation

- Faster validation of multi-file models (x2 approx.)
- Much less memory used compared to 1.6.1 (/10 approx.)
- No more "false positive" errors

2.12   Console

- Interactive console allows to directly interact with agents (experiments, simulations and any agent) and get a direct feedback on the impact of code execution using a new interpreter integrated with the console. Available in the modeling perspective (to interact with the new `gama` agent) as well as the simulation perspective (to interact with the current `experiment` agent).
- Console now accepts colored text output

2.13   Monitor view

- monitors can have colors
- monitors now have contextual menus depending on the value displayed (save as CSV, inspect, browse...)

2.14   GAMA-wide online help on the language

- A global search engine is now available in the top-right corner of the GAMA window to look for GAML idioms

2.15   Serialization

- Serialize simulations and replay them (to come)
- Serialization and deserialization of agents between simulations (to come)

2.16   Allow TCP, UDP and MQQT communications between agents in different simulations (to come)

Chapter 3

Learn GAML (Beginner -I)

If you are a beginner, the next 4 chapters will introduce you to the GAML language. To learn the language, follow this recommended sequence:

- Literals
- Types or Data Types
- File Types
- Pseudo-variables

Chapter 4

Literals

(some literal expressions are also described in data types)

A literal is a way to specify an unnamed constant value corresponding to a given data type. GAML supports various types of literals for often — or less often — used data types.

4.1   Table of contents

- Literals
    - Simple Types
    - Literal Constructors
    - Universal Literal

4.2   Simple Types

Values of simple (i.e. not composed) types can all be expressed using literal expressions. Namely:

- **bool**: `true` and `false`.
- **int**: decimal value, such as `100`, or hexadecimal value if preceded by `'#'` (e.g. `#AAAAAA`, which returns the int `11184810`)
- **float**: the value in plain digits, using `'.'` for the decimal point (e.g. `123.297`)
- **string**: a sequence of characters enclosed between quotes (`'my string'`) or double quotes (`"my string"`)

4.3   Literal Constructors

Although they are not strictly literals in the sense given above, some special constructs (called *literal constructors*) allow the modeler to declare constants of other data types. They are actually operators but can be thought of literals when used with constant operands.

- **pair**: the key and the value separated by `::` (e.g. `12::'abc'`)
- **list**: the elements, separated by commas, enclosed inside square brackets (e.g. `[12,15,15]`)
- **map**: a list of pairs (e.g. `[12::'abc', 13::'def']`)
- **point**: 2 or 3 int or float ordinates enclosed inside curly brackets (e.g. `{10.0,10.0,10.0}`)

4.4   Universal Literal

Finally, a special literal, of type `unknown`, is shared between the data types and all the agent types (aka species). Only `bool`, `int` and `float`, which do not derive from `unknown`, do not accept this literal. All the others will accept it (e.g. `string s <- nil;` is ok).

- **unknown**: `nil`, which represents the non-initialized (or, literally, *unknown*) value.

Chapter 5

Types

A variable's or expression's *type* (or *data type*) determines the values it can take, plus the operations that can be performed on or with it. GAML is a statically-typed language, which means that the type of an expression is always known at compile time, and is even enforced with casting operations. There are 4 categories of types:

- primitive types, declared as keyword in the language,
- complex types, also declared as keyword in the language,
- parametric types, a refinement of complex types (mainly children of container) that is dynamically constructed using an enclosing type, a contents type and a key type,
- species types, dynamically constructed from the species declarations made by the modeler (and the built-in species present).

The hierarchy of types in GAML (only primitive and complex types are displayed here, of course, as the other ones are model-dependent) is the following:

5.1   Table of contents

- Types (Under Construction)
  - Primitive built-in types
    * bool
    * float
    * int
    * string
  - Complex built-in types
    * agent
    * container
    * file
    * geometry
    * graph
    * list
    * map
    * matrix
    * pair
    * path
    * point
    * rgb
    * species
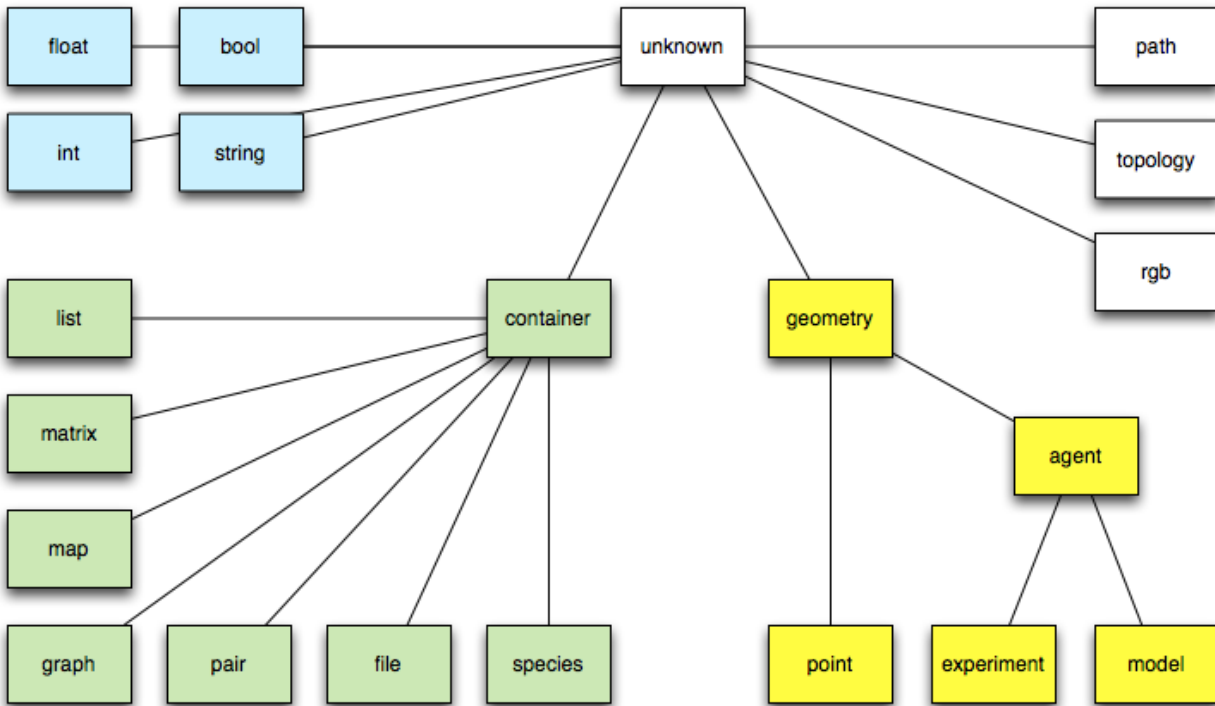

Figure 5.1: images/types_hierarchy.png

* Species names as types
* topology
  − Defining custom types

5.2   Primitive built-in types

5.2.1   bool

- **Definition:** primitive datatype providing two values: `true` or `false`.
- **Litteral declaration:** both `true` or `false` are interpreted as boolean constants.
- **Other declarations:** expressions that require a boolean operand often directly apply a casting to bool to their operand. It is a convenient way to directly obtain a bool value.

```
bool (0) -> false
```

Top of the page

5.2.2   float

- **Definition:** primitive datatype holding floating point values, its absolute value is comprised between 4.9E-324 and 1.8E308.
- **Comments:** this datatype is internally backed up by the Java double datatype.
- **Litteral declaration:** decimal notation 123.45 or exponential notation 123e45 are supported.
- **Other declarations:** expressions that require an integer operand often directly apply a casting to float to their operand. Using it is a way to obtain a float constant.

```
float (12) -> 12.0
```

Top of the page

5.2.3 int

- **Definition:** primitive datatype holding integer values comprised between -2147483648 and 2147483647 (i.e. between `-2^31` and `2^31 - 1`.
- **Comments:** this datatype is internally backed up by the Java int datatype.
- **Litteral declaration:** decimal notation like 1, 256790 or hexadecimal notation like #1209FF are automatically interpreted.
- **Other declarations:** expressions that require an integer operand often directly apply a casting to int to their operand. Using it is a way to obtain an integer constant.

```
int (234.5) -> 234.
```

Top of the page

5.2.4 string

- **Definition:** a datatype holding a sequence of characters.
- **Comments:** this datatype is internally backed up by the Java String class. However, contrary to Java, strings are considered as a primitive type, which means they do not contain character objects. This can be seen when casting a string to a list using the list operator: the result is a list of one-character strings, not a list of characters.
- **Litteral declaration:** a sequence of characters enclosed in quotes, like 'this is a string' . If one wants to literally declare strings that contain quotes, one has to double these quotes in the declaration. Strings accept escape characters like `\n` (newline), `\r` (carriage return), `\t` (tabulation), as well as any Unicode character (`\uXXXX`).
- **Other declarations:** see string
- **Example:** see string operators.

Top of the page

5.3 Complex built-in types

Contrarily to primitive built-in types, complex types have often various attributes. They can be accessed in the same way as attributes of agents:

```
complex_type nom_var <- init_var;
ltype_attr attr_var <- nom_var.attr_name;
```

For example:

```
file fileText <- file("../data/cell.Data");
bool fileTextReadable <- fileText.readable;
```

5.3.1 agent

- **Definition:** a generic datatype that represents an agent whatever its actual species.
- **Comments:** This datatype is barely used, since species can be directly used as datatypes themselves.
- **Declaration:** the agent casting operator can be applied to an int (to get the agent with this unique index), a string (to get the agent with this name).

Top of the page

5.3.2   container

- **Definition:** a generic datatype that represents a collection of data.

- **Comments:** a container variable can be a list, a matrix, a map… Conversely each list, matrix and map is a kind of container. In consequence every container can be used in container-related operators.

- **See also:** Container operators

- **Declaration:**

```
container c  <- [1,2,3];
container c  <- matrix [[1,2,3],[4,5,6]];
container c  <- map ["x"::5, "y"::12];
container c  <- list species1;
```

Top of the page

5.3.3   file

- **Definition:** a datatype that represents a file.
- **Built-in attributes:**
  - name (type = string): the name of the represented file (with its extension)
  - extension(type = string): the extension of the file
  - path (type = string): the absolute path of the file
  - readable (type = bool, read-only): a flag expressing whether the file is readable
  - writable (type = bool, read-only): a flag expressing whether the file is writable
  - exists (type = bool, read-only): a flag expressing whether the file exists
  - is_folder (type = bool, read-only): a flag expressing whether the file is folder
  - contents (type = container): a container storing the content of the file
- **Comments:** a variable with the `file` type can handle any kind of file (text, image or shape files…). The type of the `content` attribute will depend on the kind of file. Note that the allowed kinds of file are the followings:
  - text files: files with the extensions .txt, .data, .csv, .text, .tsv, .asc. The `content` is by default a list of string.
  - image files: files with the extensions .pgm, .tif, .tiff, .jpg, .jpeg, .png, .gif, .pict, .bmp. The `content` is by default a matrix of int.
  - shapefiles: files with the extension .shp. The `content` is by default a list of geometry.
  - properties files: files with the extension .properties. The `content` is by default a map of string::string.
  - folders. The `content` is by default a list of string.
- **Remark:** Files are also a particular kind of container and can thus be read, written or iterated using the container operators and commands.
- **See also:** File operators
- **Declaration:** a file can be created using the generic `file` (that opens a file in read only mode and tries to determine its contents), `folder` or the `new_folder` (to open an existing folder or create a new one) unary operators. But things can be specialized with the combination of the `read`/`write` and `image`/`text`/`shapefile`/`properties` unary operators.

```
folder(a_string)  // returns a file managing a existing folder
file(a_string) // returns any kind of file in read-only mode
read(text(a_string)) // returns a text file in read-only mode
read(image(a_string)) // does the same with an image file.
```

```
write(properties(a_string)) // returns a property file which is available for writing
                            // (if it exists, contents will be appended unless it is cleared
                            // using the standard container operations).
```

Top of the page

5.3.4 geometry

- **Definition:** a datatype that represents a vector geometry, i.e. a list of georeferenced points.
- **Built-in attributes:**
  - location (type = point): the centroid of the geometry
  - area (type = float): the area of the geometry
  - perimeter (type = float): the perimeter of the geometry
  - holes (type = list of geometry): the list of the hole inside the given geometry
  - contour (type = geometry): the exterior ring of the given geometry and of his holes
  - envelope (type = geometry): the geometry bounding box
  - width (type = float): the width of the bounding box
  - height (type = float): the height of the bounding box
  - points (type = list of point): the set of the points composing the geometry
- **Comments:** a geometry can be either a point, a polyline or a polygon. Operators working on geometries handle transparently these three kinds of geometry. The envelope (a.k.a. the bounding box) of the geometry depends on the kind of geometry:
  - If this Geometry is the empty geometry, it is an empty point.
  - If the Geometry is a point, it is a non-empty point.
  - Otherwise, it is a Polygon whose points are (minx, miny), (maxx, miny), (maxx, maxy), (minx, maxy), (minx, miny).
- **See also:** Spatial operators
- **Declaration:** geometries can be built from a point, a list of points or by using specific operators (circle, square, triangle…).

```
geometry varGeom <- circle(5);
geometry polygonGeom <- polygon([{3,5}, {5,6},{1,4}]);
```

Top of the page

5.3.5 graph

- **Definition:** a datatype that represents a graph composed of vertices linked by edges.
- **Built-in attributes:**
  - edges(type = list of agent/geometry): the list of all edges
  - vertices(type = list of agent/geometry): the list of all vertices
  - circuit (type = path): an approximate minimal traveling salesman tour (hamiltonian cycle)
  - spanning_tree (type = list of agent/geometry): minimum spanning tree of the graph, i.e. a subgraph such as every vertex lies in the tree, and as much edges lies in it but no cycles (or loops) are formed.
  - connected(type = bool): test whether the graph is connected
- **Remark:**
  - graphs are also a particular kind of container and can thus be manipulated using the container operators and commands.
  - This algorithm used to compute the circuit requires that the graph be complete and the triangle inequality exists (if x,y,z are vertices then $d(x,y)+d(y,z)<d(x,z)$ for all x,y,z then this algorithm will guarantee a hamiltonian cycle such that the total weight of the cycle is less than or equal to double the total weight of the optimal hamiltonian cycle.

– The computation of the spanning tree uses an implementation of the Kruskal's minimum spanning tree algorithm. If the given graph is connected it computes the minimum spanning tree, otherwise it computes the minimum spanning forest.
- **See also:** Graph operators
- **Declaration:** graphs can be built from a list of vertices (agents or geometries) or from a list of edges (agents or geometries) by using specific operators. They are often used to deal with a road network and are built from a shapefile.

```
create road from: shape_file_road;
graph the_graph <- as_edge_graph(road);

graph([1,9,5])          --: ([1: in[] + out[], 5: in[] + out[], 9: in[] + out[]], [])
graph([node(0), node(1), node(2)]     // if node is a species
graph(['a'::345, 'b'::13])  --:  ([b: in[] + out[b::13], a: in[] + out[a::345], 13: in[b::13] + out[],
graph(a_graph)  --: a_graph
graph(node1)    --: null
```

Top of the page

5.3.6 list

- **Definition:** a composite datatype holding an ordered collection of values.
- **Comments:** lists are more or less equivalent to instances of ArrayList in Java (although they are backed up by a specific class). They grow and shrink as needed, can be accessed via an index (see @ or index_of), support set operations (like union and difference), and provide the modeller with a number of utilities that make it easy to deal with collections of agents (see, for instance, shuffle, reverse,where,sort_by,...).
- **Remark:** lists can contain values of any datatypes, including other lists. Note, however, that due to limitations in the current parser, lists of lists cannot be declared litteraly; they have to be built using assignments. Lists are also a particular kind of container and can thus be manipulated using the container operators and commands.
- **Litteral declaration:** a set of expressions separated by commas, enclosed in square brackets, like [12, 14, 'abc', self]. An empty list is noted .
- **Other declarations:** lists can be build litteraly from a point, or a string, or any other element by using the list casting operator.

```
list (1) -> [1]

list<int> myList <- [1,2,3,4];
myList[2] => 3
```

Top of the page

5.3.7 map

- **Definition:** a composite datatype holding an ordered collection of pairs (a key, and its associated value).
- **Built-in attributes:**
    – keys (type = list): the list of all keys
    – values (type = list): the list of all values
    – pairs (type = list of pairs): the list of all pairs key::value
- **Comments:** maps are more or less equivalent to instances of Hashtable in Java (although they are backed up by a specific class).
- **Remark:** maps can contain values of any datatypes, including other maps or lists. Maps are also a particular kind of container and can thus be manipulated using the container operators and commands.

- **Litteral declaration:** a set of pair expressions separated by commas, enclosed in square brackets; each pair is represented by a key and a value sperarated by '::'. An example of map is [agentA::'big', agentB::'small', agentC::'big']. An empty map is noted .
- **Other declarations:** lists can be built litteraly from a point, or a string, or any other element by using the map casting operator.

```
map (1) -> [1::1]
map ({1,5}) -> [x::1, y::5]
[]   // empty map
```

Top of the page

5.3.8   matrix

- **Definition:** a composite datatype that represents either a two-dimension array (matrix) or a one-dimension array (vector), holding any type of data (including other matrices).
- **Comments:** Matrices are fixed-size structures that can be accessed by index (point for two-dimensions matrices, integer for vectors).
- **Litteral declaration:** Matrices cannot be defined literally. One-dimensions matrices can be built by using the matrix casting operator applied on a list. Two-dimensions matrices need to to be declared as variables first, before being filled.

```
//builds a one-dimension matrix, of size 5
matrix mat1 <- matrix ([10, 20, 30, 40, 50]);
//  builds a two-dimensions matrix with 10 columns and 5 rows, where each cell is initialized to 0.0
matrix mat2 <- 0.0 as_matrix({10,5});
// builds a two-dimensions matrix with 2 columns and 3 rows, with initialized cells
matrix mat3 <- matrix([["c11","c12","c13"],["c21","c22","c23"]]);
    -> c11;c21
       c12;c22
       c13;c23
```

Top of the page

5.3.9   pair

- **Definition:** a datatype holding a key and its associated value.
- **Built-in attributes:**
  - key (type = string): the key of the pair, i.e. the first element of the pair
  - value (type = string): the value of the pair, i.e. the second element of the pair
- **Remark:** pairs are also a particular kind of container and can thus be manipulated using the container operators and commands.
- **Litteral declaration:** a pair is defined by a key and a value sperarated by '::'.
- **Other declarations:** a pair can also be built from:
  - a point,
  - a map (in this case the first element of the pair is the list of all the keys of the map and the second element is the list of all the values of the map),
  - a list (in this case the two first element of the list are used to built the pair)

```
pair testPair <- "key"::56;
pair testPairPoint <- {3,5};            // 3::5
pair testPairList2 <- [6,7,8];          // 6::7
pair testPairMap <- [2::6,5::8,12::45]; // [12,5,2]::[45,8,6]
```

Top of the page

5.3.10   path

- **Definition:** a datatype representing a path linking two agents or geometries in a graph.
- **Built-in attributes:**
  - source (type = point): the source point, i.e. the first point of the path
  - target (type = point): the target point, i.e. the last point of the path
  - graph (type = graph): the current topology (in the case it is a spatial graph), null otherwise
  - edges (type = list of agents/geometries) : the edges of the graph composing the path
  - vertices (type = list of agents/geometries) : the vertices of the graph composing the path
  - segments (type = list of geometries): the list of the geometries composing the path
  - shape (type = geometry) : the global geometry of the path (polyline)
- **Comments:** the path created between two agents/geometries or locations will strongly depends on the topology in which it is created.
- **Remark:** a path is **immutable**, i.e. it can not be modified after it is created.
- **Declaration:** paths are very barely defined litterally. We can nevertheless use the `path` unary operator on a list of points to build a path. Operators dedicated to the computation of paths (such as path_to or path_between) are often used to build a path.

```
path([{1,5},{2,9},{5,8}]) // a path from {1,5} to {5,8} through {2,9}
```

```
geometry rect <- rectangle(5);
geometry poly <- polygon([{10,20},{11,21},{10,21},{11,22}]);
path pa <- rect path_to poly;  // built a path between rect and poly, in the topolopy
                                        // of the current agent (i.e. a line in a& continuous topol
                                        // a path in a graph  in a graph topology )
```

```
a_topology path_between a_container_of_geometries // idem with an explicit topology and the possiblity
                                        // to have more than 2 geometries
                                        // (the path is then built incrementally)
```

```
path_between (a_graph, a_source, a_target) // idem with a the given graph as topology
```

Top of the page

5.3.11   point

- **Definition:** a datatype normally holding two positive float values. Represents the absolute coordinates of agents in the model.
- **Built-in attributes:**
  - x (type = float): coordinate of the point on the x-axis
  - y (type = float): coordinate of the point on the y-axis
- **Comments:** point coordinates should be positive, if a negative value is used in its declaration, the point is built with the absolute value.
- **Remark:** points are particular cases of geometries and containers. Thus they have also all the built-in attributes of both the geometry and the container datatypes and can be used with every kind of operator or command admitting geometry and container.
- **Litteral declaration:** two numbers, separated by a comma, enclosed in braces, like {12.3, 14.5}
- **Other declarations:** points can be built litteraly from a list, or from an integer or float value by using the point casting operator.

```
point ([12,123.45]) -> {12.0, 123.45}
point (2) -> {2.0, 2.0}
```

Top of the page

5.3.12 rgb

- **Definition:** a datatype that represents a color in the RGB space.
- **Built-in attributes:**
  - red(type = int): the red component of the color
  - green(type = int): the green component of the color
  - blue(type = int): the blue component of the color
  - darker(type = rgb): a new color that is a darker version of this color
  - brighter(type = rgb): a new color that is a brighter version of this color
- **Remark:** rgbs are also a particular kind of container and can thus be manipulated using the container operators and commands.
- **Litteral declaration:** there exist lot of ways to declare a color. We use the `rgb` casting operator applied to:
  - a string. The allowed color names are the constants defined in the Color Java class, i.e.: black, blue, cyan, darkGray, lightGray, gray, green, magenta, orange, pink, red, white, yellow.
  - a list. The integer value associated to the three first elements of the list are used to define the three red (element 0 of the list), green (element 1 of the list) and blue (element 2 of the list) components of the color.
  - a map. The red, green, blue compoenents take the value associated to the keys "r", "g", "b" in the map.
  - an integer <- the decimal integer is translated into a hexadecimal <- OxRRGGBB. The red (resp. green, blue) component of the color take the value RR (resp. GG, BB) translated in decimal.
  - Since GAMA 1.6.1, colors can be directly obtained like units, by using the ° or # symbol followed by the name in lowercase of one of the 147 CSS colors (see http://www.cssportal.com/css3-color-names/).
- **Declaration:**

```
rgb cssRed <- #red;    // Since 1.6.1
rgb testColor <- rgb('white');               // rgb [255,255,255]
rgb test <- rgb(3,5,67);                 // rgb [3,5,67]
rgb te <- rgb(340);                      // rgb [0,1,84]
rgb tete <- rgb(["r"::34, "g"::56, "b"::345]); // rgb [34,56,255]
```

Top of the page

5.3.13 species

- Definition: a generic datatype that represents a species
- **Built-in attributes:**
  - topology (type=topology): the topology is which lives the population of agents
- Comments: this datatype is actually a "meta-type". It allows to manipulate (in a rather limited fashion, however) the species themselves as any other values.
- Litteral declaration: the name of a declared species is already a litteral declaration of species.
- Other declarations: the species casting operator, or its variant called species_of can be applied to an agent in order to get its species.

Top of the page

5.3.14 Species names as types

Once a species has been declared in a model, it automatically becomes a datatype. This means that : * It can be used to declare variables, parameters or constants, * It can be used as an operand to commands or operators that require species parameters, * It can be used as a casting operator (with the same capabilities as the built-in type agent)

In the simple following example, we create a set of "humans" and initialize a random "friendship network" among them. See how the name of the species, human, is used in the create command, as an argument to the list casting operator, and as the type of the variable named friend.

```
global {
    init {
        create human number: 10;
        ask human {
            friend <- one_of (human - self);
        }
    }
}
entities {
    species human {
        human friend <- nil;
    }
}
```

Top of the page

5.3.15   topology

- **Definition:** a topology is basically on neighborhoods, distance,… structures in which agents evolves. It is the environment or the context in which all these values are computed. It also provides the access to the spatial index shared by all the agents. And it maintains a (eventually dynamic) link with the 'environment' which is a geometrical border.
- **Built-in attributes:**
  - places(type = container): the collection of places (geometry) defined by this topology.
  - environment(type = geometry): the environment of this topology (i.e. the geometry that defines its boundaries)
- **Comments:** the attributes `places` depends on the kind of the considered topolopy. For continuous topologies, it is a list with their environment. For discrete topologies, it can be any of the container supporting the inclusion of geometries (list, graph, map, matrix)
- **Remark:** There exist various kinds of topology: continuous topology and discrete topology (e.g. grid, graph…)
- **Declaration:** To create a topology, we can use the `topology` unary casting operator applied to:
  - an agent: returns a continuous topology built from the agent's geometry
  - a species name: returns the topology defined for this species population
  - a geometry: returns a continuous topology built on this geometry
  - a geometry container (list, map, shapefile): returns an half-discrete (with corresponding places), half-continuous topology (to compute distances…)
  - a geometry matrix (i.e. a grid): returns a grid topology which computes specifically neighborhood and distances
  - a geometry graph: returns a graph topology which computes specifically neighborhood and distances More complex topologies can also be built using dedicated operators, e.g. to decompose a geometry…

Top of the page

5.4   Defining custom types

Sometimes, besides the species of agents that compose the model, it can be necessary to declare custom datatypes. Species serve this purpose as well, and can be seen as "classes" that can help to instantiate

simple "objects". In the following example, we declare a new kind of "object", bottle, that lacks the skills habitually associated with agents (moving, visible, etc.), but can nevertheless group together attributes and behaviors within the same closure. The following example demonstrates how to create the species:

```
species bottle {
    float volume <- 0.0 max:1 min:0.0;
    bool is_empty -> {volume = 0.0};
    action fill {
        volume <- 1.0;
    }
}
```

How to use this species to declare new bottles :

```
create bottle {
    volume <- 0.5;
}
```

And how to use bottles as any other agent in a species (a drinker owns a bottle; when he gets thirsty, it drinks a random quantity from it; when it is empty, it refills it):

```
species drinker {
     ...
    bottle my_bottle<- nil;
    float quantity <- rnd (100) / 100;
    bool thirsty <- false update: flip (0.1);
    ...
    action drink {
        if condition: ! bottle.is_empty {
            bottle.volume <-bottle.volume - quantity;
            thirsty <- false;
        }
    }
    ...
    init {
         create bottle return: created_bottle;
            volume <- 0.5;
        }
         my_bottle <- first(created_bottle);
    }
    ...
    reflex filling_bottle when: bottle.is_empty {
        ask  my_bottle {
            do fill;
        }
    }
    ...
    reflex drinking when: thirsty {
        do drink;
    }
}
```

Top of the page

Chapter 6

File Types

GAMA provides modelers with a generic type for files called **file**. It is possible to load a file using the *file* operator:

```
file my_file <- file("../includes/data.csv");
```

However, internally, GAMA makes the difference between the different types of files. Indeed, for instance:

```
global {
    init {
        file my_file <- file("../includes/data.csv");
        loop el over: my_file {
            write el;
        }
    }
}
```

will give:

```
sepallength
sepalwidth
petallength
petalwidth
type
5.1
3.5
1.4
0.2
Iris-setosa
4.9
3.0
1.4
0.2
Iris-setosa
...
```

Indeed, the content of CSV file is a matrix: each row of the matrix is a line of the file; each column of the matrix is value delimited by the separator (by default ",").

In contrary:

```
global {
    init {
```

```
        file my_file <- file("../includes/data.shp");
        loop el over: my_file {
            write el;
        }
    }
}
```

will give:

```
Polygon
Polygon
Polygon
Polygon
Polygon
Polygon
Polygon
```

The content of a shapefile is a list of geometries corresponding to the objects of the shapefile.

In order to know how to load a file, GAMA analyzes its extension. For instance for a file with a ".csv" extension, GAMA knows that the file is a **csv** one and will try to split each line with the , separator. However, if the modeler wants to split each line with a different separator (for instance **;**) or load it as a text file, he/she will have to use a specific file operator.

Indeed, GAMA integrates specific operators corresponding to different types of files.

6.1   Table of contents

- File Types
  - Text File

    * Extensions
    * Content
    * Operators
  - Image File
    * Extensions
    * Content
    * Operators
  - SVG File
    * Extensions

6.2 Text File

6.2.1 Extensions

Here the list of possible extensions for text file: * "txt" * "data" * "csv" * "text" * "tsv" * "xml"

Note that when trying to define the type of a file with the default file loading operator (**file**), GAMA will first try to test the other type of file. For example, for files with ".csv" extension, GAMA will cast them as csv file and not as text file.

6.2.2 Content

The content of a text file is a list of string corresponding to each line of the text file. For example:

```
global {
    init {
        file my_file <- text_file("../includes/data.txt");
        loop el over: my_file {
            write el;
        }
    }
}
```

will give:

```
sepallength,sepalwidth,petallength,petalwidth,type
5.1,3.5,1.4,0.2,Iris-setosa
4.9,3.0,1.4,0.2,Iris-setosa
4.7,3.2,1.3,0.2,Iris-setosa
```

6.2.3 Operators

List of operators related to text files: * **text_file(string path)**: load a file (with an authorized extension) as a text file. * **text_file(string path, list content)**: load a file (with an authorized extension) as a text

file and fill it with the given content. * **is_text(op)**: tests whether the operand is a text file

6.3   CSV File

6.3.1   Extensions

Here the list of possible extensions for csv file: * "csv" * "tsv"

6.3.2   Content

The content of a csv file is a matrix of string: each row of the matrix is a line of the file; each column of the matrix is value delimited by the separator (by default ","). For example:

```
global {
    init {
        file my_file <- csv_file("../includes/data.csv");
        loop el over: my_file {
            write el;
        }
    }
}
```

will give:

```
sepallength
sepalwidth
petallength
petalwidth
type
5.1
3.5
1.4
0.2
Iris-setosa
4.9
3.0
1.4
0.2
Iris-setosa
...
```

6.3.3   Operators

List of operators related to csv files: * **csv_file(string path)**: load a file (with an authorized extension) as a csv file with default separator (","). * **csv_file(string path, string separator)**: load a file (with an authorized extension) as a csv file with the given separator.

```
file my_file <- csv_file("../includes/data.csv", ";");
```

- **csv_file(string path, matrix content)**: load a file (with an authorized extension) as a csv file and fill it with the given content.
- **is_csv(op)**: tests whether the operand is a csv file

6.4 Shapefile

Shapefiles are classical GIS data files. A shapefile is not simple file, but a set of several files (source: wikipedia): * Mandatory files : * .shp — shape format; the feature geometry itself * .shx — shape index format; a positional index of the feature geometry to allow seeking forwards and backwards quickly * .dbf — attribute format; columnar attributes for each shape, in dBase IV format

- Optional files :
    - .prj — projection format; the coordinate system and projection information, a plain text file describing the projection using well-known text format
    - .sbn and .sbx — a spatial index of the features
    - .fbn and .fbx — a spatial index of the features for shapefiles that are read-only
    - .ain and .aih — an attribute index of the active fields in a table
    - .ixs — a geocoding index for read-write shapefiles
    - .mxs — a geocoding index for read-write shapefiles (ODB format)
    - .atx — an attribute index for the .dbf file in the form of shapefile.columnname.atx (ArcGIS 8 and later)
    - .shp.xml — geospatial metadata in XML format, such as ISO 19115 or other XML schema
    - .cpg — used to specify the code page (only for .dbf) for identifying the character encoding to be used

More details about shapefiles can be found here.

6.4.1 Extensions

Here the list of possible extension for shapefile: * "shp"

6.4.2 Content

The content of a shapefile is a list of geometries corresponding to the objects of the shapefile. For example:

```
global {
    init {
        file my_file <- shape_file("../includes/data.shp");
        loop el over: my_file {
            write el;
        }
    }
}
```

will give:

```
Polygon
Polygon
Polygon
Polygon
Polygon
Polygon
Polygon
...
```

Note that the attributes of each object of the shapefile is stored in their corresponding GAMA geometry. The operator "get" (or "read") allows to get the value of a corresponding attributes.

For example:

```
file my_file <- shape_file("../includes/data.shp");
write "my_file: " + my_file.contents;
loop el over: my_file {
    write (el get "TYPE");
}
```

6.4.3   Operators

List of operators related to shapefiles: * **shape_file(string path)**: load a file (with an authorized extension) as a shapefile with default projection (if a prj file is defined, use it, otherwise use the default projection defined in the preference). * **shape_file(string path, string code)**: load a file (with an authorized extension) as a shapefile with the given projection (GAMA will automatically decode the code. For a list of the possible projections see: http://spatialreference.org/ref/) * **shape_file(string path, int EPSG_ID)**: load a file (with an authorized extension) as a shapefile with the given projection (GAMA will automatically decode the epsg code. For a list of the possible projections see: http://spatialreference.org/ref/)

```
file my_file <- shape_file("../includes/data.shp", "EPSG:32601");
```

- **shape_file(string path, list content)**: load a file (with an authorized extension) as a shapefile and fill it with the given content.
- **is_shape(op)**: tests whether the operand is a shapefile

6.5   OSM File

OSM (Open Street Map) is a collaborative project to create a free editable map of the world. The data produced in this project (OSM File) represent physical features on the ground (e.g., roads or buildings) using tags attached to its basic data structures (its nodes, ways, and relations). Each tag describes a geographic attribute of the feature being shown by that specific node, way or relation (source: openstreetmap.org).

More details about OSM data can be found here.

6.5.1   Extensions

Here the list of possible extension for shapefile: * "osm" * "pbf" * "bz2" * "gz"

6.5.2   Content

The content of a OSM data is a list of geometries corresponding to the objects of the OSM file. For example:

```
global {
    init {
        file my_file <- osm_file("../includes/data.gz");
        loop el over: my_file {
            write el;
        }
    }
}
```

will give:

```
Point
Point
Point
```

```
Point
Point
LineString
LineString
Polygon
Polygon
Polygon
...
```

Note that like for shapefiles, the attributes of each object of the osm file is stored in their corresponding GAMA geometry. The operator "get" (or "read") allows to get the value of a corresponding attributes.

6.5.3 Operators

List of operators related to osm file: * **osm_file(string path)**: load a file (with an authorized extension) as a osm file with default projection (if a prj file is defined, use it, otherwise use the default projection defined in the preference). In this case, all the nodes and ways of the OSM file will becomes a geometry. * **osm_file(string path, string code)**: load a file (with an authorized extension) as a osm file with the given projection (GAMA will automatically decode the code. For a list of the possible projections see: http://spatialreference.org/ref/). In this case, all the nodes and ways of the OSM file will becomes a geometry. * **osm_file(string path, int EPSG_ID)**: load a file (with an authorized extension) as a osm file with the given projection (GAMA will automatically decode the epsg code. For a list of the possible projections see: http://spatialreference.org/ref/). In this case, all the nodes and ways of the OSM file will becomes a geometry.

```
file my_file <- osm_file("../includes/data.gz", "EPSG:32601");
```

- **osm_file(string path, map filter)**: load a file (with an authorized extension) as a osm file with default projection (if a prj file is defined, use it, otherwise use the default projection defined in the preference). In this case, only the elements with the defined values are loaded from the file. "' //map used to filter the object to build from the OSM file according to attributes. map filtering <- map(["highway"::["primary", "secondary", "tertiary", "motorway", "living_street","residential", "unclassified"], "building"::["yes"]]);

//OSM file to load file osmfile <- file

Chapter 7

Pseudo-variables

The expressions known as **pseudo-variables** are special read-only variables that are not declared anywhere (at least not in a species), and which represent a value that changes depending on the context of execution.

7.1 Table of contents

7.2 self

The pseudo-variable `self` always holds a reference to the agent executing the current statement.

- Example (sets the `friend` attribute of another random agent of the same species to `self` and conversely):

```
friend potential_friend <- one_of (species(self) - self);
if potential_friend != nil {
    potential_friend.friend <- self;
    friend <- potential_friend;
}
```

7.3 super

The pseudo-variable `super` behaves exactly in the same way as `self` except when calling an action, in which case it represents an indirection to the parent species. It is mainly used for allowing to call inherited actions within redefined ones. For instance:

```
species parent {

    int add(int a, int b) {
        return a + b;
```

```
    }

}

species child parent: parent {

    int add(int a, int b) {
        // Calls the action defined in 'parent' with modified arguments
        return super.add(a + 20, b + 20);
    }

}
```

7.4   myself

`myself` plays the same role as `self` but in remotely-executed code (`ask`, `create`, `capture` and `release` statements), where it represents the *calling* agent when the code is executed by the *remote* agent.

- Example (asks the first agent of my species to set its color to my color):

```
ask first (species (self)){
    color <- myself.color;
}
```

- Example (create 10 new agents of the species of my species, share the energy between them, turn them towards me, and make them move 4 times to get closer to me):

```
create species (self) number: 10 {
    energy <- myself.energy / 10.0;
    loop times: 4 {
        heading <- towards (myself);
        do move;
    }
}
```

7.5   each

`each` is available only in the right-hand argument of iterators. It is a pseudo-variable that represents, in turn, each of the elements of the left-hand container. It can then take any type depending on the context.

- Example:

```
list<string> names <- my_species collect each.name;  // each is of type my_species
int max <- max(['aa', 'bbb', 'cccc'] collect length(each)); // each is of type string
```

Chapter 8

Learn GAML (Beginner -II)

If you are a beginner, the next 7 chapters will introduce you to functions and statements in GAML language. Before you read these chapters it is important you know what are data types. To learn the language, follow this recommended sequence:

- Operators (9-15) : This includes 6 chapters introducing you to all the operators (A to Z) in GAMA. Go first to the chapter **opeators by categories** to get a feel of the scope of operators available. Operators are typically like functions in other languages. They accept one or more arguments of the basic or complex data types and return a result in one of the data types.

- Statements (16) : Statement is a one-line sequence of keywords (commands) guided with controlling arguments (facets) that operate on one of the data types or a combination of operators and data types. A typical example is:

- if you want an agent1 at location A to go to a location B, then the following is a valid GAML statement

```
do goto target:B
```

- if you want an agent1 at location A to go to a location B with a speed of S, then the following is a GAML valid statement

```
do goto target:B speed:S
```

- if you want an agent1 at location A to go to a location B with a speed of S on a graph G, then the following is a GAML valid statement

```
do goto target:B speed:S on:G
```

Chapter 9

Chapter 10

Operators (A to A)

10.0.1   -

10.0.1.1   Possible use:

- - (int) —> int
- - (point) —> point
- - (float) —> float
- date - date —> float
- - (date , date) —> float
- matrix - float —> matrix
- - (matrix , float) —> matrix
- rgb - int —> rgb
- - (rgb , int) —> rgb
- float - matrix —> matrix
- - (float , matrix) —> matrix
- map - map —> map
- - (map , map) —> map
- int - matrix —> matrix
- - (int , matrix) —> matrix
- int - int —> int
- - (int , int) —> int
- int - float —> float
- - (int , float) —> float
- point - int —> point
- - (point , int) —> point
- point - float —> point
- - (point , float) —> point
- map - pair —> map
- - (map , pair) —> map
- date - float —> date
- - (date , float) —> date
- geometry - geometry —> geometry
- - (geometry , geometry) —> geometry
- matrix - int —> matrix
- - (matrix , int) —> matrix

- `rgb - rgb` —> `rgb`
- `- (rgb , rgb)` —> `rgb`
- `float - float` —> `float`
- `- (float , float)` —> `float`
- `matrix - matrix` —> `matrix`
- `- (matrix , matrix)` —> `matrix`
- `date - int` —> `date`
- `- (date , int)` —> `date`
- `geometry - float` —> `geometry`
- `- (geometry , float)` —> `geometry`
- `geometry - container<geometry>` —> `geometry`
- `- (geometry , container<geometry>)` —> `geometry`
- `point - point` —> `point`
- `- (point , point)` —> `point`
- `list - unknown` —> `list`
- `- (list , unknown)` —> `list`
- `species - agent` —> `list`
- `- (species , agent)` —> `list`
- `container - container` —> `list`
- `- (container , container)` —> `list`
- `float - int` —> `float`
- `- (float , int)` —> `float`

10.0.1.2   Result:

Returns the difference of the two operands. If it is used as an unary operator, it returns the opposite of the operand.

10.0.1.3   Comment:

The behavior of the operator depends on the type of the operands.

10.0.1.4   Special cases:

- if the left operand is a species and the right operand is an agent of the species, - returns a list containing all the agents of the species minus this agent

- if both operands are containers and the right operand is empty, - returns the left operand

- if both operands are dates, returns the duration in seconds between date2 and date1. To obtain a more precise duration, in milliseconds, use milliseconds_between(date1, date2)

```
float var0 <- date('2000-01-02') - date('2000-01-01'); // var0 equals 86400
```

- if one operand is a color and the other an integer, returns a new color resulting from the subtraction of each component of the color with the right operand

```
rgb var1 <- rgb([255, 128, 32]) - 3; // var1 equals rgb([252,125,29])
```

- if one operand is a matrix and the other a number (float or int), performs a normal arithmetic difference of the number with each element of the matrix (results are float if the number is a float.

```
matrix var2 <- 3.5 - matrix([[2,5],[3,4]]); // var2 equals matrix([[1.5,-1.5],[0.5,-0.5]])
```

- if both operands are numbers, performs a normal arithmetic difference and returns a float if one of them is a float.

```
int var3 <- 1 - 1; // var3 equals 0
```

- if left-hand operand is a point and the right-hand a number, returns a new point with each coordinate as the difference of the operand coordinate with this number.

```
point var4 <- {1, 2} - 4.5; // var4 equals {-3.5, -2.5, -4.5}
point var5 <- {1, 2} - 4; // var5 equals {-3.0,-2.0,-4.0}
```

- if both operands are a point, a geometry or an agent, returns the geometry resulting from the difference between both geometries

```
geometry var6 <- geom1 - geom2; // var6 equals a geometry corresponding to difference between geom1 and
```

- if both operands are colors, returns a new color resulting from the subtraction of the two operands, component by component

```
rgb var7 <- rgb([255, 128, 32]) - rgb('red'); // var7 equals rgb([0,128,32])
```

- if one of the operands is a date and the other a number, returns a date corresponding to the date minus the given number as duration (in seconds)

```
date var8 <- date('2000-01-01') - 86400; // var8 equals date('1999-12-31')
```

- if the left-hand operand is a geometry and the right-hand operand a float, returns a geometry corresponding to the left-hand operand (geometry, agent, point) reduced by the right-hand operand distance

```
geometry var9 <- shape - 5; // var9 equals a geometry corresponding to the geometry of the agent applyi
```

- if the right-operand is a list of points, geometries or agents, returns the geometry resulting from the difference between the left-geometry and all of the right-geometries

```
geometry var10 <- rectangle(10,10) - [circle(2), square(2)]; // var10 equals rectangle(10,10) - (circle
```

- if both operands are points, returns their difference (coordinates per coordinates).

```
point var11 <- {1, 2} - {4, 5}; // var11 equals {-3.0, -3.0}
```

- if the left operand is a list and the right operand is an object of any type (except list), - returns a list containing the elements of the left operand minus all the occurrences of this object

```
list<int> var12 <- [1,2,3,4,5,6] - 2; // var12 equals [1,3,4,5,6]
list<int> var13 <- [1,2,3,4,5,6] - 0; // var13 equals [1,2,3,4,5,6]
```

- if both operands are containers, returns a new list in which all the elements of the right operand have been removed from the left one

```
list<int> var14 <- [1,2,3,4,5,6] - [2,4,9]; // var14 equals [1,3,5,6]
list<int> var15 <- [1,2,3,4,5,6] - [0,8]; // var15 equals [1,2,3,4,5,6]
```

10.0.1.5 Examples:

```
int var16 <- - (-56); // var16 equals 56
map var17 <- ['a'::1,'b'::2] - ['b'::2]; // var17 equals ['a'::1]
map var18 <- ['a'::1,'b'::2] - ['b'::2,'c'::3]; // var18 equals ['a'::1]
point var19 <- -{3.0,5.0}; // var19 equals {-3.0,-5.0}
point var20 <- -{1.0,6.0,7.0}; // var20 equals {-1.0,-6.0,-7.0}
map var21 <- ['a'::1,'b'::2] - ('b'::2); // var21 equals ['a'::1]
map var22 <- ['a'::1,'b'::2] - ('c'::3); // var22 equals ['a'::1,'b'::2]
float var23 <- 1.0 - 1; // var23 equals 0.0
float var24 <- 3.7 - 1.2; // var24 equals 2.5
float var25 <- 3 - 1.2; // var25 equals 1.8
```

10.0.1.6 See also:

milliseconds_between, -, +, *, /,

10.0.2   :

10.0.2.1 Possible use:

- unknown : unknown —> unknown
- : (unknown , unknown) —> unknown

10.0.2.2 See also:

?,

10.0.3   ::

10.0.3.1 Possible use:

- any expression :: any expression —> pair
- :: (any expression , any expression) —> pair

10.0.3.2 Result:

produces a new pair combining the left and the right operands

10.0.3.3 Special cases:

- nil is not acceptable as a key (although it is as a value). If such a case happens, :: will throw an appropriate error

---

10.0.4 !

10.0.4.1 Possible use:

- ! (bool) —> bool

10.0.4.2 Result:

opposite boolean value.

10.0.4.3 Special cases:

- if the parameter is not boolean, it is casted to a boolean value.

10.0.4.4 Examples:

```
bool var0 <- ! (true); // var0 equals false
```

10.0.4.5 See also:

bool, and, or,

10.0.5 !=

10.0.5.1 Possible use:

- unknown != unknown —> bool
- != (unknown , unknown) —> bool
- float != int —> bool
- != (float , int) —> bool
- int != float —> bool
- != (int , float) —> bool
- float != float —> bool
- != (float , float) —> bool
- date != date —> bool
- != (date , date) —> bool

10.0.5.2 Result:

true if both operands are different, false otherwise

10.0.5.3 Examples:

```
bool var0 <- [2,3] != [2,3]; // var0 equals false
bool var1 <- [2,4] != [2,3]; // var1 equals true
bool var2 <- 3.0 != 3; // var2 equals false
bool var3 <- 4.7 != 4; // var3 equals true
bool var4 <- 3 != 3.0; // var4 equals false
bool var5 <- 4 != 4.7; // var5 equals true
bool var6 <- 3.0 != 3.0; // var6 equals false
bool var7 <- 4.0 != 4.7; // var7 equals true
bool var8 <- #now != #now minus_hours 1; // var8 equals true
```

10.0.5.4 See also:

=, >, <, >=, <=,

10.0.6   ?

10.0.6.1 Possible use:

- `bool` **?** `any expression` —> `unknown`
- **?** (`bool` , `any expression`) —> `unknown`

10.0.6.2 Result:

It is used in combination with the : operator: if the left-hand operand evaluates to true, returns the value of the left-hand operand of the :, otherwise that of the right-hand operand of the :

10.0.6.3 Comment:

These functional tests can be combined together.

10.0.6.4 Examples:

```
list<string> var0 <- [10, 19, 43, 12, 7, 22] collect ((each > 20) ? 'above' : 'below'); // var0 equals
```

10.0.6.5 See also:

:,

10.0.7 /

10.0.7.1 Possible use:

- `float / int` —> `float`
- `/ (float , int)` —> `float`
- `point / float` —> `point`
- `/ (point , float)` —> `point`
- `float / float` —> `float`
- `/ (float , float)` —> `float`
- `int / float` —> `float`
- `/ (int , float)` —> `float`
- `matrix / float` —> `matrix`
- `/ (matrix , float)` —> `matrix`
- `rgb / int` —> `rgb`
- `/ (rgb , int)` —> `rgb`
- `matrix / int` —> `matrix`
- `/ (matrix , int)` —> `matrix`
- `matrix / matrix` —> `matrix`
- `/ (matrix , matrix)` —> `matrix`
- `rgb / float` —> `rgb`
- `/ (rgb , float)` —> `rgb`
- `point / int` —> `point`
- `/ (point , int)` —> `point`
- `int / int` —> `float`
- `/ (int , int)` —> `float`

10.0.7.2 Result:

Returns the division of the two operands.

10.0.7.3 Special cases:

- if the right-hand operand is equal to zero, raises a "Division by zero" exception

- if the left operand is a point, returns a new point with coordinates divided by the right operand

```
point var0 <- {5, 7.5} / 2.5; // var0 equals {2, 3}
point var1 <- {2,5} / 4; // var1 equals {0.5,1.25}
```

- if one operand is a color and the other an integer, returns a new color resulting from the division of each component of the color by the right operand

```
rgb var2 <- rgb([255, 128, 32]) / 2; // var2 equals rgb([127,64,16])
```

- if one operand is a color and the other a double, returns a new color resulting from the division of each component of the color by the right operand. The result on each component is then truncated.

```
rgb var3 <- rgb([255, 128, 32]) / 2.5; // var3 equals rgb([102,51,13])
```

- if both operands are numbers (float or int), performs a normal arithmetic division and returns a float.

```
float var4 <- 3 / 5.0; // var4 equals 0.6
```

10.0.7.4 See also:

*, +, -,

10.0.8 .

10.0.8.1 Possible use:

- `matrix . matrix —> matrix`
- `. (matrix , matrix) —> matrix`
- `agent . any expression —> unknown`
- `. (agent , any expression) —> unknown`

10.0.8.2 Result:

It has two different uses: it can be the dot product between 2 matrices or return an evaluation of the expression (right-hand operand) in the scope the given agent.

10.0.8.3 Special cases:

- if the agent is nil or dead, throws an exception

- if both operands are matrix, returns the dot product of them

```
matrix var0 <- matrix([[1,1],[1,2]]) . matrix([[1,1],[1,2]]); // var0 equals matrix([[2,3],[3,5]])
```

- if the left operand is an agent, it evaluates of the expression (right-hand operand) in the scope the given agent

```
unknown var1 <- agent1.location; // var1 equals the location of the agent agent1
```

10.0.9 ^

10.0.9.1 Possible use:

- `int ^ float —> float`
- `^ (int , float) —> float`
- `int ^ int —> float`
- `^ (int , int) —> float`
- `float ^ int —> float`
- `^ (float , int) —> float`
- `float ^ float —> float`
- `^ (float , float) —> float`

10.0.9.2 Result:

Returns the value (always a float) of the left operand raised to the power of the right operand.

10.0.9.3 Special cases:

- if the right-hand operand is equal to 0, returns 1

- if it is equal to 1, returns the left-hand operand.

- Various examples of power

```
float var0 <- 2 ^ 3; // var0 equals 8.0
```

10.0.9.4 Examples:

```
float var1 <- 4.84 ^ 0.5; // var1 equals 2.2
```

10.0.9.5 See also:

*, sqrt,

10.0.10 @

Same signification as at

10.0.11 *

10.0.11.1 Possible use:

- `float * float —> float`
- `* (float , float) —> float`
- `int * int —> int`
- `* (int , int) —> int`
- `int * matrix —> matrix`
- `* (int , matrix) —> matrix`

10.0.11.2   Result:

Returns the product of the two operands.

10.0.11.3   Special cases:

- if both operands are numbers (float or int), performs a normal arithmetic product and returns a float
  if one of them is a float.

```
int var1 <- 1 * 1; // var1 equals 1
```

- if one operand is a matrix and the other a number (float or int), performs a normal arithmetic product
  of the number with each element of the matrix (results are float if the number is a float.

```
matrix<float> m <- (3.5 * matrix([[2,5],[3,4]]));    //m equals matrix([[7.0,17.5],[10.5,14]])
```

- if one operand is a color and the other an integer, returns a new color resulting from the product of
  each component of the color with the right operand (with a maximum value at 255)

```
rgb var3 <- rgb([255, 128, 32]) * 2; // var3 equals rgb([255,255,64])
```

- if both operands are points, returns their scalar product

```
float var4 <- {2,5} * {4.5, 5}; // var4 equals 34.0
```

- if the left-hand operand is a geometry and the right-hand operand a float, returns a geometry corre-
  sponding to the left-hand operand (geometry, agent, point) scaled by the right-hand operand coefficient

```
geometry var5 <- circle(10) * 2; // var5 equals circle(20)
geometry var6 <- (circle(10) * 2).location with_precision 9; // var6 equals (circle(20)).location with_
float var7 <- (circle(10) * 2).height with_precision 9; // var7 equals (circle(20)).height with_precisi
```

- if the left-hand operator is a point and the right-hand a number, returns a point with coordinates
  multiplied by the number

```
point var8 <- {2,5} * 4; // var8 equals {8.0, 20.0}
point var9 <- {2, 4} * 2.5; // var9 equals {5.0, 10.0}
```

- if the left-hand operand is a geometry and the right-hand operand a point, returns a geometry corresponding to the left-hand operand (geometry, agent, point) scaled by the right-hand operand coefficients in the 3 dimensions

```
geometry var10 <- shape * {0.5,0.5,2}; // var10 equals a geometry corresponding to the
```

10.0.11.4 Examples:

```
float var0 <- 2.5 * 2; // var0 equals 5.0
```

10.0.12.2   Result:

Returns the sum, union or concatenation of the two operands.

10.0.12.3   Special cases:

- if one of the operands is nil, + throws an error

- if both operands are species, returns a special type of list called meta-population

- if one operand is a color and the other an integer, returns a new color resulting from the sum of each component of the color with the right operand

```
rgb var0 <- rgb([255, 128, 32]) + 3; // var0 equals rgb([255,131,35])
```

- if both operands are points, returns their sum.

```
point var1 <- {1, 2} + {4, 5}; // var1 equals {5.0, 7.0}
```

- if the right operand is an object of any type (except a container), + returns a list of the elements of the left operand, to which this object has been added

```
list<int> var2 <- [1,2,3,4,5,6] + 2; // var2 equals [1,2,3,4,5,6,2]
list<int> var3 <- [1,2,3,4,5,6] + 0; // var3 equals [1,2,3,4,5,6,0]
```

- if the right-operand is a point, a geometry or an agent, returns the geometry resulting from the union between both geometries

```
geometry var4 <- geom1 + geom2; // var4 equals a geometry corresponding to union between geom1 and geom2
```

- if the left-hand operand is a point and the right-hand a number, returns a new point with each coordinate as the sum of the operand coordinate with this number.

```
point var5 <- {1, 2} + 4; // var5 equals {5.0, 6.0,4.0}
point var6 <- {1, 2} + 4.5; // var6 equals {5.5, 6.5,4.5}
```

- if both operands are numbers (float or int), performs a normal arithmetic sum and returns a float if one of them is a float.

```
int var7 <- 1 + 1; // var7 equals 2
```

- if one of the operands is a date and the other a number, returns a date corresponding to the date plus the given number as duration (in seconds)

```
date var8 <- date('2000-01-01') + 86400; // var8 equals date('2000-01-02')
```

- if one operand is a matrix and the other a number (float or int), performs a normal arithmetic sum of the number with each element of the matrix (results are float if the number is a float.

```
matrix var9 <- 3.5 + matrix([[2,5],[3,4]]); // var9 equals matrix([[5.5,8.5],[6.5,7.5]])
```

- if the left-hand operand is a geometry and the right-hand operand a float, returns a geometry corresponding to the left-hand operand (geometry, agent, point) enlarged by the right-hand operand distance. The number of segments used by default is 8 and the end cap style is #round

```
geometry var10 <- circle(5) + 5; // var10 equals circle(10)
```

- if the left-hand operand is a string, returns the concatenation of the two operands (the left-hand one beind casted into a string)

```
string var11 <- "hello " + 12; // var11 equals "hello 12"
```

- if both operands are list, +returns the concatenation of both lists.

```
list<int> var12 <- [1,2,3,4,5,6] + [2,4,9]; // var12 equals [1,2,3,4,5,6,2,4,9]
list<int> var13 <- [1,2,3,4,5,6] + [0,8]; // var13 equals [1,2,3,4,5,6,0,8]
```

- if both operands are colors, returns a new color resulting from the sum of the two operands, component by component

```
rgb var14 <- rgb([255, 128, 32]) + rgb('red'); // var14 equals rgb([255,128,32])
```

- if the left-hand operand is a geometry and the right-hand operands a float, an integer and one of #round, #square or #flat, returns a geometry corresponding to the left-hand operand (geometry, agent, point) enlarged by the first right-hand operand (distance), using a number of segments equal to the second right-hand operand and a flat, square or round end cap style

```
geometry var15 <- circle(5) + (5,32,#round); // var15 equals circle(10)
```

- if the left-hand operand is a geometry and the right-hand operands a float and an integer, returns a geometry corresponding to the left-hand operand (geometry, agent, point) enlarged by the first right-hand operand (distance), using a number of segments equal to the second right-hand operand

```
geometry var16 <- circle(5) + (5,32); // var16 equals circle(10)
```

10.0.12.4 Examples:

```
float var17 <- 1.0 + 1; // var17 equals 2.0
float var18 <- 1.0 + 2.5; // var18 equals 3.5
map var19 <- ['a'::1,'b'::2] + ('c'::3); // var19 equals ['a'::1,'b'::2,'c'::3]
map var20 <- ['a'::1,'b'::2] + ('c'::3); // var20 equals ['a'::1,'b'::2,'c'::3]
map var21 <- ['a'::1,'b'::2] + ['c'::3]; // var21 equals ['a'::1,'b'::2,'c'::3]
map var22 <- ['a'::1,'b'::2] + [5::3.0]; // var22 equals ['a'::1,'b'::2,5::3.0]
```

10.0.12.5 See also:

-, *, /,

10.0.13 <

10.0.13.1 Possible use:

- `date < date` —> `bool`
- `< (date , date)` —> `bool`
- `float < int` —> `bool`
- `< (float , int)` —> `bool`
- `float < float` —> `bool`

- `< (int , float)` —> `bool`
- `string < string` —> `bool`
- `< (string , string)` —> `bool`

10.0.13.2 Result:

true if the left-hand operand is less than the right-hand operand, false otherwise.

10.0.13.3 Special cases:

- if one of the operands is nil, returns false

- if both operands are points, returns true if and only if the left component (x) of the left operand if less than or equal to x of the right one and if the right component (y) of the left operand is greater than or equal to y of the right one.

```
bool var5 <- {5,7} < {4,6}; // var5 equals false
bool var6 <- {5,7} < {4,8}; // var6 equals false
```

- if both operands are String, uses a lexicographic comparison of two strings

```
bool var7 <- 'abc' < 'aeb'; // var7 equals true
```

10.0.13.4 Examples:

```
bool var0 <- #now < #now minus_hours 1; // var0 equals false
bool var1 <- 3.5 < 7; // var1 equals true
bool var2 <- 3.5 < 7.6; // var2 equals true
bool var3 <- 3 < 7; // var3 equals true
bool var4 <- 3 < 2.5; // var4 equals false

bool var8 <- 3.5 >= 3.5; // var8 equals true
```

10.0.18.5 See also:

$>$, $<$, $<=$, $=$, $!=$,

10.0.19 abs

10.0.19.1 Possible use:

- **abs** (float) —> float
- **abs** (int) —> int

10.0.19.2 Result:

Returns the absolute value of the operand (so a positive int or float depending on the type of the operand).

10.0.19.3 Examples:

```
float var0 <- abs (200 * -1 + 0.5); // var0 equals 199.5
int var1 <- abs (-10); // var1 equals 10
int var2 <- abs (10); // var2 equals 10
```

10.0.20 `accumulate`

10.0.20.1 Possible use:

- container **accumulate** any expression —> list
- **accumulate** (container , any expression) —> list

10.0.20.2 Result:

returns a new flat list, in which each element is the evaluation of the right-hand operand. If this evaluation
returns a list, the elements of this result are added directly to the list returned

10.0.20.3 Comment:

accumulate is dedicated to the application of a same computation on each element of a container (and returns
a list). In the right-hand operand, the keyword each can be used to represent, in turn, each of the left-hand
operand elements.

10.0.20.4 Examples:

```
list var0 <- [a1,a2,a3] accumulate (each neighbors_at 10); // var0 equals a flat list of all the neighb
list<int> var1 <- [1,2,4] accumulate ([2,4]); // var1 equals [2,4,2,4,2,4]
list<int> var2 <- [1,2,4] accumulate (each * 2); // var2 equals [2,4,8]
```

10.0.20.5 See also:

collect,

10.0.21 `acos`

10.0.21.1 Possible use:

- **acos** (int) —> float
- **acos** (float) —> float

10.0.21.2 Result:

Returns the value (in the interval [0,180], in decimal degrees) of the arccos of the operand (which should be
in [-1,1]).

10.0.21.3 Special cases:

- if the right-hand operand is outside of the [-1,1] interval, returns NaN

10.0.21.4 Examples:

```
float var0 <- acos (0); // var0 equals 90.0
```

10.0.21.5 See also:

asin, atan, cos,

10.0.22 `action`

10.0.22.1 Possible use:

- **action** (any) —> action

10.0.22.2 Result:

Casts the operand into the type action

10.0.23 `add_3Dmodel`

10.0.23.1 Possible use:

- **add_3Dmodel** (msi.gaml.types.GamaKmlExport, point, float, float, string) —> msi.gaml.types.GamaKmlExport
- **add_3Dmodel** (msi.gaml.types.GamaKmlExport, point, float, float, string, date, date) —> msi.gaml.types.GamaKmlExport

10.0.23.2 Result:

the kml export manager with new 3D model: take the following argument: (kml, location (point),orientation (float), scale (float), file_path (string)) the kml export manager with new 3D model: take the following argument: (kml, location (point),orientation (float), scale (float), file_path (string), begin date, end date)

10.0.32 `add_node`

10.0.32.1 Possible use:

- graph **add_node** geometry —> graph
- **add_node** (graph , geometry) —> graph

10.0.32.2 Result:

adds a node in a graph.

10.0.32.3 Examples:

```
graph var0 <- graph add_node node(0) ; // var0 equals the graph with node(0)
```

10.0.32.4 See also:

add_edge, graph,

10.0.33 `add_point`

10.0.33.1 Possible use:

- geometry **add_point** point —> geometry
- **add_point** (geometry , point) —> geometry

10.0.33.2 Result:

A new geometry resulting from the addition of the right point (coordinate) to the left-hand geometry. Note that adding a point to a line or polyline will always return a closed contour. Also note that the position at which the added point will appear in the geometry is not necessarily the last one, as points are always ordered in a clockwise fashion in geometries

10.0.33.3 Examples:

```
geometry var0 <- polygon([{10,10},{10,20},{20,20}]) add_point {20,10}; // var0 equals polygon([{10,10},
```

10.0.34 `add_seconds`

Same signification as +

10.0.35 **add_weeks**

Same signification as plus_weeks

10.0.36 **add_years**

Same signification as plus_years

10.0.37 **adjacency**

10.0.37.1 Possible use:

- **adjacency** (graph) —> matrix<float>

10.0.37.2 Result:

adjacency matrix of the given graph.

10.0.38 **after**

10.0.38.1 Possible use:

- **after** (date) —> bool
- any expression **after** date —> bool
- **after** (any expression , date) —> bool

10.0.38.2 Result:

Returns true if the current_date of the model is strictly after the date passed in argument. Synonym of 'current_date > argument'. Can be used in its composed form with 2 arguments to express the lower boundary for the computation of a frequency. Note that only dates strictly after this one will be tested against the frequency

10.0.38.3 Examples:

reflex when: after(starting_date) {}   // this reflex will always be run after the first step reflex wh

---

10.0.39 **agent**

10.0.39.1 Possible use:

- **agent** (any) —> agent

10.0.39.2 Result:

Casts the operand into the type agent

10.0.40 `agent_closest_to`

10.0.40.1 Possible use:

- `agent_closest_to` (unknown) —> `agent`

10.0.40.2 Result:

An agent, the closest to the operand (casted as a geometry).

10.0.40.3 Comment:

the distance is computed in the topology of the calling agent (the agent in which this operator is used), with the distance algorithm specific to the topology.

10.0.40.4 Examples:

```
agent var0 <- agent_closest_to(self); // var0 equals the closest agent to the agent applying the operat
```

10.0.40.5 See also:

neighbors_at, neighbors_of, agents_inside, agents_overlapping, closest_to, inside, overlapping,

---

10.0.41 `agent_farthest_to`

10.0.41.1 Possible use:

- `agent_farthest_to` (unknown) —> `agent`

10.0.41.2 Result:

An agent, the farthest to the operand (casted as a geometry).

10.0.41.3 Comment:

the distance is computed in the topology of the calling agent (the agent in which this operator is used), with the distance algorithm specific to the topology.

10.0.41.4 Examples:

```
agent var0 <- agent_farthest_to(self); // var0 equals the farthest agent to the agent applying the opera
```

10.0.41.5 See also:

neighbors_at, neighbors_of, agents_inside, agents_overlapping, closest_to, inside, overlapping, agent_closest_to, farthest_to,

---

10.0.42 `agent_from_geometry`

10.0.42.1 Possible use:

- path **agent_from_geometry** geometry —> agent
- **agent_from_geometry** (path , geometry) —> agent

10.0.42.2 Result:

returns the agent corresponding to given geometry (right-hand operand) in the given path (left-hand operand).

10.0.42.3 Special cases:

- if the left-hand operand is nil, returns nil

10.0.42.4 Examples:

```
geometry line <- one_of(path_followed.segments); road ag <- road(path_followed agent_from_geometry line)
```

10.0.42.5 See also:

path,

10.0.43 `agents_at_distance`

10.0.43.1 Possible use:

- **agents_at_distance** (float) —> list

10.0.43.2 Result:

A list of agents situated at a distance lower than the right argument.

10.0.43.3 Examples:

```
list var0 <- agents_at_distance(20); // var0 equals all the agents (excluding the caller) which distanc
```

10.0.43.4 See also:

neighbors_at, neighbors_of, agent_closest_to, agents_inside, closest_to, inside, overlapping, at_distance,

---

10.0.44 `agents_inside`

10.0.44.1 Possible use:

- **agents_inside** (unknown) —> list<agent>

10.0.44.2 Result:

A list of agents covered by the operand (casted as a geometry).

10.0.44.3 Examples:

```
list<agent> var0 <- agents_inside(self); // var0 equals the agents that are covered by the shape of the
```

10.0.44.4 See also:

agent_closest_to, agents_overlapping, closest_to, inside, overlapping,

---

10.0.45 `agents_overlapping`

10.0.45.1 Possible use:

- **agents_overlapping** (unknown) —> list<agent>

10.0.45.2 Result:

A list of agents overlapping the operand (casted as a geometry).

10.0.45.3 Examples:

```
list<agent> var0 <- agents_overlapping(self); // var0 equals the agents that overlap the shape of the ag
```

10.0.45.4   See also:

neighbors_at, neighbors_of, agent_closest_to, agents_inside, closest_to, inside, overlapping, at_distance,

---

10.0.46   `all_pairs_shortest_path`

10.0.46.1   Possible use:

- **all_pairs_shortest_path** (graph) —> matrix<int>

10.0.46.2   Result:

returns the successor matrix of shortest paths between all node pairs (rows: source, columns: target): a cell
(i,j) will thus contains the next node in the shortest path between i and j.

10.0.46.3   Examples:

matrix<int> var0 <- all_pairs_shortest_paths(my_graph); // var0 equals shortest_paths_matrix will conta

---

10.0.47   `alpha_index`

10.0.47.1   Possible use:

- **alpha_index** (graph) —> float

10.0.47.2   Result:

returns the alpha index of the graph (measure of connectivity which evaluates the number of cycles in a
graph in comparison with the maximum number of cycles. The higher the alpha index, the more a network
is connected: alpha = nb_cycles / (2*S-5) - planar graph)

10.0.47.3   Examples:

float var1 <- alpha_index(graphEpidemio); // var1 equals the alpha index of the graph

10.0.47.4   See also:

beta_index, gamma_index, nb_cycles, connectivity_index,

10.0.48 among

10.0.48.1 Possible use:

- int **among** container —> list
- **among** (int , container) —> list

10.0.48.2 Result:

Returns a list of length the value of the left-hand operand, containing random elements from the right-hand operand. As of GAMA 1.6, the order in which the elements are returned can be different than the order in which they appear in the right-hand container

10.0.48.3 Special cases:

- if the right-hand operand is empty, among returns a new empty list. If it is nil, it throws an error.

- if the left-hand operand is greater than the length of the right-hand operand, among returns the right-hand operand (converted as a list). If it is smaller or equal to zero, it returns an empty list

10.0.48.4 Examples:

```
list<int> var0 <- 3 among [1,2,4,3,5,7,6,8]; // var0 equals [1,2,8] (for example)
list var1 <- 3 among g2; // var1 equals [node6,node11,node7]
list var2 <- 3 among list(node); // var2 equals [node1,node11,node4]
list<int> var3 <- 1 among [1::2,3::4]; // var3 equals 2 or 4
```

10.0.49 and

10.0.49.1 Possible use:

- bool **and** any expression —> bool
- **and** (bool , any expression) —> bool

10.0.49.2 Result:

a bool value, equal to the logical and between the left-hand operand and the right-hand operand.

10.0.49.3 Comment:

both operands are always casted to bool before applying the operator. Thus, an expression like (1 and 0) is accepted and returns false.

10.0.49.4 See also:

bool, or, !,

10.0.50 `and`

10.0.50.1 Possible use:

- predicate **and** predicate —> predicate
- **and** (predicate , predicate) —> predicate

10.0.50.2 Result:

create a new predicate from two others by including them as subintentions

10.0.50.3 Examples:

```
predicate1 and predicate2
```

10.0.51 `angle_between`

10.0.51.1 Possible use:

- **angle_between** (point, point, point) —> float

10.0.51.2 Result:

the angle between vectors P0P1 and P0P2 (P0, P1, P2 being the three point operands)

10.0.51.3 Examples:

```
float var0 <- angle_between({5,5},{10,5},{5,10}); // var0 equals 90
```

10.0.52 `any`

Same signification as one_of

10.0.53 any_location_in

10.0.53.1 Possible use:

- **any_location_in** (geometry) —> point

10.0.53.2 Result:

A point inside (or touching) the operand-geometry.

10.0.53.3 Examples:

```
point var0 <- any_location_in(square(5)); // var0 equals a point in the square, for example : {3,4.6}.
```

10.0.53.4 See also:

closest_points_with, farthest_point_to, points_at,

10.0.54 any_point_in

Same signification as any_location_in

10.0.55 append_horizontally

10.0.55.1 Possible use:

- matrix **append_horizontally** matrix —> matrix
- **append_horizontally** (matrix , matrix) —> matrix
- matrix **append_horizontally** matrix —> matrix
- **append_horizontally** (matrix , matrix) —> matrix

10.0.55.2 Result:

A matrix resulting from the concatenation of the rows of the two given matrices. If not both numerical or both object matrices, returns the first matrix.

10.0.55.3 Examples:

```
matrix var0 <- matrix([[1.0,2.0],[3.0,4.0]]) append_horizontally matrix([[1,2],[3,4]]); // var0 equals
```

10.0.56   `append_vertically`

10.0.56.1   Possible use:

- matrix **append_vertically** matrix —> matrix
- **append_vertically** (matrix , matrix) —> matrix
- matrix **append_vertically** matrix —> matrix
- **append_vertically** (matrix , matrix) —> matrix

10.0.56.2   Result:

A matrix resulting from the concatenation of the columns of the two given matrices. If not both numerical or both object matrices, returns the first matrix.

10.0.56.3   Examples:

```
matrix var0 <- matrix([[1,2],[3,4]]) append_vertically matrix([[1,2],[3,4]]); // var0 equals matrix([[1
```

10.0.57   `arc`

10.0.57.1   Possible use:

- **arc** (float, float, float) —> geometry
- **arc** (float, float, float, bool) —> geometry

10.0.57.2   Result:

An arc, which radius is equal to the first operand, heading to the second and amplitude the third An arc, which radius is equal to the first operand, heading to the second, amplitude to the third and a boolean indicating whether to return a linestring or a polygon to the fourth

10.0.57.3   Comment:

the center of the arc is by default the location of the current agent in which has been called this operator. This operator returns a polygon by default.the center of the arc is by default the location of the current agent in which has been called this operator.

10.0.57.4   Special cases:

- returns a point if the radius operand is lower or equal to 0.

- returns a point if the radius operand is lower or equal to 0.

10.0.57.5   Examples:

```
geometry var0 <- arc(4,45,90); // var0 equals a geometry as an arc of radius 4, in a direction of 45Â°
geometry var1 <- arc(4,45,90, false); // var1 equals a geometry as an arc of radius 4, in a direction o
```

10.0.57.6   See also:

around, cone, line, link, norm, point, polygon, polyline, super_ellipse, rectangle, square, circle, ellipse, triangle,

---

10.0.58   `around`

10.0.58.1   Possible use:

- `float` **`around`** `unknown` —> `geometry`
- **`around`** `(float , unknown)` —> `geometry`

10.0.58.2   Result:

A geometry resulting from the difference between a buffer around the right-operand casted in geometry at a distance left-operand (right-operand buffer left-operand) and the right-operand casted as geometry.

10.0.58.3   Special cases:

- returns a circle geometry of radius right-operand if the left-operand is nil

10.0.58.4   Examples:

```
geometry var0 <- 10 around circle(5); // var0 equals the ring geometry between 5 and 10.
```

10.0.58.5   See also:

circle, cone, line, link, norm, point, polygon, polyline, rectangle, square, triangle,

---

10.0.59   `as`

10.0.59.1   Possible use:

- `unknown` **`as`** `msi.gaml.types.IType` —> `unknown`
- **`as`** `(unknown , msi.gaml.types.IType)` —> `unknown`

10.0.59.2 Result:

casting of the first argument into a given type

10.0.59.3 Comment:

It is equivalent to the application of the type operator on the left operand.

10.0.59.4 Examples:

```
int var0 <- 3.5 as int; // var0 equals int(3.5)
```

10.0.60 `as_4_grid`

10.0.60.1 Possible use:

- geometry **as_4_grid** point —> matrix
- **as_4_grid** (geometry , point) —> matrix

10.0.60.2 Result:

A matrix of square geometries (grid with 4-neighborhood) with dimension given by the right-hand operand ({nb_cols, nb_lines}) corresponding to the square tessellation of the left-hand operand geometry (geometry, agent)

10.0.60.3 Examples:

```
matrix var0 <- self as_4_grid {10, 5}; // var0 equals the matrix of square geometries (grid with 4-neigh
```

10.0.60.4 See also:

as_grid, as_hexagonal_grid,

10.0.61 `as_distance_graph`

10.0.61.1 Possible use:

- container **as_distance_graph** map —> graph
- **as_distance_graph** (container , map) —> graph
- container **as_distance_graph** float —> graph
- **as_distance_graph** (container , float) —> graph
- **as_distance_graph** (container, float, species) —> graph

10.0.61.2 Result:

creates a graph from a list of vertices (left-hand operand). An edge is created between each pair of vertices close enough (less than a distance, right-hand operand).

10.0.61.3 Comment:

as_distance_graph is more efficient for a list of points than as_intersection_graph.

10.0.61.4 Examples:

`list(ant) as_distance_graph 3.0`

10.0.61.5 See also:

as_intersection_graph, as_edge_graph,

10.0.62 `as_driving_graph`

10.0.62.1 Possible use:

- container **as_driving_graph** container —> graph
- **as_driving_graph** (container , container) —> graph

10.0.62.2 Result:

creates a graph from the list/map of edges given as operand and connect the node to the edge

10.0.62.3 Examples:

`as_driving_graph(road,node)  --:  build a graph while using the road agents as edges and the node agents`

10.0.62.4 See also:

as_intersection_graph, as_distance_graph, as_edge_graph,

10.0.63 `as_edge_graph`

10.0.63.1 Possible use:

- **as_edge_graph** (map) —> graph
- **as_edge_graph** (container) —> graph
- container **as_edge_graph** float —> graph
- **as_edge_graph** (container , float) —> graph

10.0.63.2 Result:

creates a graph from the list/map of edges given as operand

10.0.63.3 Special cases:

- if the operand is a map, the graph will be built by creating edges from pairs of the map

```
graph var0 <- as_edge_graph([{1,5}::{12,45},{12,45}::{34,56}]); // var0 equals a graph with these three
```

- if the operand is a list and a tolerance (max distance in meters to consider that 2 points are the same node) is given, the graph will be built with elements of the list as edges and two edges will be connected by a node if the distance between their extremity (first or last points) are at distance lower or equal to the tolerance

```
graph var1 <- as_edge_graph([line([{1,5},{12,45}]),line([{13,45},{34,56}])],1); // var1 equals a graph w
```

- if the operand is a list, the graph will be built with elements of the list as edges

```
graph var2 <- as_edge_graph([line([{1,5},{12,45}]),line([{12,45},{34,56}])]); // var2 equals a graph wi
```

10.0.63.4 See also:

as_intersection_graph, as_distance_graph,

10.0.64 `as_grid`

10.0.64.1 Possible use:

- geometry **as_grid** point —> matrix
- **as_grid** (geometry , point) —> matrix

10.0.64.2 Result:

A matrix of square geometries (grid with 8-neighborhood) with dimension given by the right-hand operand ({nb_cols, nb_lines}) corresponding to the square tessellation of the left-hand operand geometry (geometry, agent)

10.0.64.3 Examples:

```
matrix var0 <- self as_grid {10, 5}; // var0 equals a matrix of square geometries (grid with 8-neighbor
```

10.0.64.4 See also:

as_4_grid, as_hexagonal_grid,

10.0.65 `as_hexagonal_grid`

10.0.65.1 Possible use:

- geometry **as_hexagonal_grid** point —> list<geometry>
- **as_hexagonal_grid** (geometry , point) —> list<geometry>

10.0.65.2 Result:

A list of geometries (hexagonal) corresponding to the hexagonal tesselation of the first operand geometry

10.0.65.3 Examples:

list<geometry> var0 <- self as_hexagonal_grid {10, 5}; // var0 equals list of geometries (hexagonal) co

10.0.65.4 See also:

as_4_grid, as_grid,

10.0.66 `as_int`

10.0.66.1 Possible use:

- string **as_int** int —> int
- **as_int** (string , int) —> int

10.0.66.2 Result:

parses the string argument as a signed integer in the radix specified by the second argument.

10.0.66.3 Special cases:

- if the left operand is nil or empty, as_int returns 0

- if the left operand does not represent an integer in the specified radix, as_int throws an exception

10.0.66.4 Examples:

```
int var0 <- '20' as_int 10; // var0 equals 20
int var1 <- '20' as_int 8; // var1 equals 16
int var2 <- '20' as_int 16; // var2 equals 32
int var3 <- '1F' as_int 16; // var3 equals 31
int var4 <- 'hello' as_int 32; // var4 equals 18306744
```

10.0.66.5 See also:

int,

10.0.67 `as_intersection_graph`

10.0.67.1 Possible use:

- container **as_intersection_graph** float —> graph
- **as_intersection_graph** (container , float) —> graph

10.0.67.2 Result:

creates a graph from a list of vertices (left-hand operand). An edge is created between each pair of vertices with an intersection (with a given tolerance).

10.0.67.3 Comment:

as_intersection_graph is more efficient for a list of geometries (but less accurate) than as_distance_graph.

10.0.67.4 Examples:

list(ant) as_intersection_graph 0.5

10.0.67.5 See also:

as_distance_graph, as_edge_graph,

10.0.68 `as_map`

10.0.68.1 Possible use:

- container **as_map** any expression —> map
- **as_map** (container , any expression) —> map

10.0.68.2 Result:

produces a new map from the evaluation of the right-hand operand for each element of the left-hand operand

10.0.68.3 Comment:

the right-hand operand should be a pair

10.0.68.4 Special cases:

- if the left-hand operand is nil, as_map throws an error.

10.0.68.5 Examples:

```
map<int,int> var0 <- [1,2,3,4,5,6,7,8] as_map (each::(each * 2)); // var0 equals [1::2, 2::4, 3::6, 4::8
map<int,int> var1 <- [1::2,3::4,5::6] as_map (each::(each * 2)); // var1 equals [2::4, 4::8, 6::12]
```

10.0.69 `as_matrix`

10.0.69.1 Possible use:

- unknown **as_matrix** point —> matrix
- **as_matrix** (unknown , point) —> matrix

10.0.69.2 Result:

casts the left operand into a matrix with right operand as preferred size

10.0.69.3 Comment:

This operator is very useful to cast a file containing raster data into a matrix.Note that both components of
the right operand point should be positive, otherwise an exception is raised.The operator as_matrix creates
a matrix of preferred size. It fills in it with elements of the left operand until the matrix is full If the size is
to short, some elements will be omitted. Matrix remaining elements will be filled in by nil.

10.0.69.4 Special cases:

- if the right operand is nil, as_matrix is equivalent to the matrix operator

10.0.69.5 See also:

matrix,

10.0.70 `as_path`

10.0.70.1 Possible use:

- list<geometry> **as_path** graph —> path
- **as_path** (list<geometry> , graph) —> path

10.0.70.2 Result:

create a graph path from the list of shape

10.0.70.3 Examples:

```
path var0 <- [road1,road2,road3] as_path my_graph; // var0 equals a path road1->road2->road3 of my_graph
```

10.0.71 `asin`

10.0.71.1 Possible use:

- **asin** (float) —> float
- **asin** (int) —> float

10.0.71.2 Result:

the arcsin of the operand

10.0.71.3 Special cases:

- if the right-hand operand is outside of the [-1,1] interval, returns NaN

10.0.71.4 Examples:

```
float var0 <- asin (0); // var0 equals 0.0
float var1 <- asin (90); // var1 equals #nan
```

10.0.71.5 See also:

acos, atan, sin,

10.0.72 `at`

10.0.72.1 Possible use:

- container<KeyType,ValueType> **at** KeyType —> ValueType
- **at** (container<KeyType,ValueType> , KeyType) —> ValueType
- string **at** int —> string
- **at** (string , int) —> string

10.0.72.2   Result:

the element at the right operand index of the container

10.0.72.3   Comment:

The first element of the container is located at the index 0. In addition, if the user tries to get the element at
an index higher or equals than the length of the container, he will get an IndexOutOfBoundException.The
at operator behavior depends on the nature of the operand

10.0.72.4   Special cases:

- if it is a file, at returns the element of the file content at the index specified by the right operand

- if it is a population, at returns the agent at the index specified by the right operand

- if it is a graph and if the right operand is a node, at returns the in and out edges corresponding to
  that node

- if it is a graph and if the right operand is an edge, at returns the pair node_out::node_in of the edge

- if it is a graph and if the right operand is a pair node1::node2, at returns the edge from node1 to
  node2 in the graph

- if it is a list or a matrix, at returns the element at the index specified by the right operand

```
int var0 <- [1, 2, 3] at 2; // var0 equals 3
point var1 <- [{1,2}, {3,4}, {5,6}] at 0; // var1 equals {1.0,2.0}
```

10.0.72.5   Examples:

```
string var2 <- 'abcdef' at 0; // var2 equals 'a'
```

10.0.72.6   See also:

contains_all, contains_any,

10.0.73   at_distance

10.0.73.1   Possible use:

- container<agent> **at_distance** float —> list<geometry>
- **at_distance** (container<agent> , float) —> list<geometry>

10.0.73.2 Result:

A list of agents or geometries among the left-operand list that are located at a distance $<=$ the right operand from the caller agent (in its topology)

10.0.73.3 Examples:

```
list<geometry> var0 <- [ag1, ag2, ag3] at_distance 20; // var0 equals the agents of the list located at
```

10.0.73.4 See also:

neighbors_at, neighbors_of, agent_closest_to, agents_inside, closest_to, inside, overlapping,

---

10.0.74 at_location

10.0.74.1 Possible use:

- geometry **at_location** point —> geometry
- **at_location** (geometry , point) —> geometry

10.0.74.2 Result:

A geometry resulting from the tran of a translation to the right-hand operand point of the left-hand operand (geometry, agent, point)

10.0.74.3 Examples:

```
geometry var0 <- self at_location {10, 20}; // var0 equals the geometry resulting from a translation to
```

10.0.75 atan

10.0.75.1 Possible use:

- **atan** (float) —> float
- **atan** (int) —> float

10.0.75.2 Result:

Returns the value (in the interval [-90,90], in decimal degrees) of the arctan of the operand (which can be any real number).

10.0.75.3   Examples:

```
float var0 <- atan (1); // var0 equals 45.0
```

10.0.75.4   See also:

acos, asin, tan,

10.0.76   `atan2`

10.0.76.1   Possible use:

- `float` **atan2** `float` —> `float`
- **atan2** (`float` , `float`) —> `float`

10.0.76.2   Result:

the atan2 value of the two operands.

10.0.76.3   Comment:

The function atan2 is the arctangent function with two arguments. The purpose of using two arguments instead of one is to gather information on the signs of the inputs in order to return the appropriate quadrant of the computed angle, which is not possible for the single-argument arctangent function.

10.0.76.4   Examples:

```
float var0 <- atan2 (0,0); // var0 equals 0.0
```

10.0.76.5   See also:

atan, acos, asin,

10.0.77   `attributes`

10.0.77.1   Possible use:

- **attributes** (`any`) —> `attributes`

10.0.77.2   Result:

Casts the operand into the type attributes

10.0.78 `auto_correlation`

10.0.78.1 Possible use:

- container **auto_correlation** int —> float
- **auto_correlation** (container , int) —> float

10.0.78.2 Result:

Returns the auto-correlation of a data sequence

Chapter 11

Operators (B to C)

11.0.1 BDIPlan

11.0.1.1 Possible use:

- **BDIPlan** (any) —> BDIPlan

11.0.1.2 Result:

Casts the operand into the type BDIPlan

11.0.2 before

11.0.2.1 Possible use:

- **before** (date) —> bool
- any expression **before** date —> bool
- **before** (any expression , date) —> bool

11.0.2.2 Result:

Returns true if the current_date of the model is strictly before the date passed in argument. Synonym of 'current_date < argument'

11.0.2.3 Examples:

```
reflex when: before(starting_date) {}   // this reflex will never be run
```

11.0.3 beta

11.0.3.1 Possible use:

- float **beta** float —> float
- **beta** (float , float) —> float

11.0.3.2 Result:

Returns the beta function with arguments a, b.

11.0.4 beta_index

11.0.4.1 Possible use:

- **beta_index** (graph) —> float

11.0.4.2 Result:

returns the beta index of the graph (Measures the level of connectivity in a graph and is expressed by the relationship between the number of links (e) over the number of nodes (v) : beta = e/v.

11.0.4.3 Examples:

```
graph graphEpidemio <- graph([]);
float var1 <- beta_index(graphEpidemio); // var1 equals the beta index of the graph
```

11.0.4.4 See also:

alpha_index, gamma_index, nb_cycles, connectivity_index,

11.0.5 between

11.0.5.1 Possible use:

- date **between** date —> bool
- **between** (date , date) —> bool
- **between** (any expression, date, date) —> bool
- **between** (int, int, int) —> bool
- **between** (date, date, date) —> bool
- **between** (float, float, float) —> bool

11.0.5.2 Result:

returns true the first integer operand is bigger than the second integer operand and smaller than the third integer operand

returns true if the first float operand is bigger than the second float operand and smaller than the third float operand

11.0.5.3 Special cases:

- returns true if the first operand is between the two dates passed in arguments (both exclusive). The version with 2 arguments compares the current_date with the 2 others

```
bool var0 <- (date('2016-01-01') between(date('2000-01-01'), date('2020-02-02'))); // var0 equals true/
```

- returns true if the first operand is between the two dates passed in arguments (both exclusive). Can be combined with 'every' to express a frequency between two dates

```
bool var3 <- (date('2016-01-01') between(date('2000-01-01'), date('2020-02-02'))); // var3 equals true/
```

11.0.5.4 Examples:

```
bool var6 <- between(5, 1, 10); // var6 equals true
bool var7 <- between(5.0, 1.0, 10.0); // var7 equals true
```

11.0.6 `betweenness_centrality`

11.0.6.1 Possible use:

- **betweenness_centrality** (graph) —> map

11.0.6.2 Result:

returns a map containing for each vertex (key), its betweenness centrality (value): number of shortest paths passing through each vertex

11.0.6.3 Examples:

```
graph graphEpidemio <- graph([]);
map var1 <- betweenness_centrality(graphEpidemio); // var1 equals the betweenness centrality index of th
```

11.0.7 `biggest_cliques_of`

11.0.7.1   Possible use:

- `biggest_cliques_of` (graph) —> list<list>

11.0.7.2   Result:

returns the biggest cliques of a graph using the Bron-Kerbosch clique detection algorithm

11.0.7.3   Examples:

```
graph my_graph <- graph([]);
list<list> var1 <- biggest_cliques_of (my_graph); // var1 equals the list of the biggest cliques as lis
```

11.0.7.4   See also:

maximal_cliques_of,

11.0.8   `binomial`

11.0.8.1   Possible use:

- int `binomial` float —> int
- `binomial` (int , float) —> int

11.0.8.2   Result:

A value from a random variable following a binomial distribution. The operands represent the number of experiments n and the success probability p.

11.0.8.3   Comment:

The binomial distribution is the discrete probability distribution of the number of successes in a sequence of n independent yes/no experiments, each of which yields success with probability p, cf. Binomial distribution on Wikipedia.

11.0.8.4   Examples:

```
int var0 <- binomial(15,0.6); // var0 equals a random positive integer
```

11.0.8.5   See also:

poisson, gauss,

11.0.9 `binomial_coeff`

11.0.9.1 Possible use:

- int **binomial_coeff** int —> float
- **binomial_coeff** (int , int) —> float

11.0.9.2 Result:

Returns n choose k as a double. Note the integerization of the double return value.

11.0.10 `binomial_complemented`

11.0.10.1 Possible use:

- **binomial_complemented** (int, int, float) —> float

11.0.10.2 Result:

Returns the sum of the terms k+1 through n of the Binomial probability density, where n is the number of trials and P is the probability of success in the range 0 to 1.

11.0.11 `binomial_sum`

11.0.11.1 Possible use:

- **binomial_sum** (int, int, float) —> float

11.0.11.2 Result:

Returns the sum of the terms 0 through k of the Binomial probability density, where n is the number of trials and p is the probability of success in the range 0 to 1.

11.0.12 `blend`

11.0.12.1 Possible use:

- rgb **blend** rgb —> rgb
- **blend** (rgb , rgb) —> rgb
- **blend** (rgb, rgb, float) —> rgb

11.0.12.2 Result:

Blend two colors with an optional ratio (c1 * r + c2 * (1 - r)) between 0 and 1

11.0.12.3   Special cases:

- If the ratio is omitted, an even blend is done

```
rgb var1 <- blend(#red, #blue); // var1 equals to a color very close to the purple
```

11.0.12.4   Examples:

```
rgb var3 <- blend(#red, #blue, 0.3); // var3 equals to a color between the purple and the blue
```

11.0.12.5   See also:

rgb, hsb,

11.0.13   `bool`

11.0.13.1   Possible use:

- `bool` (any) —> `bool`

11.0.13.2   Result:

Casts the operand into the type bool

11.0.14   `box`

11.0.14.1   Possible use:

- `box` (point) —> `geometry`
- `box` (float, float, float) —> `geometry`

11.0.14.2   Result:

A box geometry which side sizes are given by the operands.

11.0.14.3   Comment:

the center of the box is by default the location of the current agent in which has been called this operator.the center of the box is by default the location of the current agent in which has been called this operator.

11.0.14.4 Special cases:

- returns nil if the operand is nil.

- returns nil if the operand is nil.

11.0.14.5 Examples:

```
geometry var0 <- box(10, 5 , 5); // var0 equals a geometry as a rectangle with width = 10, height = 5 de
geometry var1 <- box({10, 5 , 5}); // var1 equals a geometry as a rectangle with width = 10, height = 5
```

11.0.14.6 See also:

around, circle, sphere, cone, line, link, norm, point, polygon, polyline, square, cube, triangle,

---

11.0.15 `brewer_colors`

11.0.15.1 Possible use:

- **brewer_colors** (string) —> list<rgb>
- string **brewer_colors** int —> list<rgb>
- **brewer_colors** (string , int) —> list<rgb>

11.0.15.2 Result:

Build a list of colors of a given type (see website http://colorbrewer2.org/). The list of palettes can be obtained by calling brewer_palettes Build a list of colors of a given type (see website http://colorbrewer2. org/) with a given number of classes

11.0.15.3 Examples:

```
list<rgb> var0 <- list<rgb> colors <- brewer_colors("OrRd");; // var0 equals a list of 6 blue colors
list<rgb> var1 <- list<rgb> colors <- brewer_colors("Pastel1", 5);; // var1 equals a list of 5 sequentia
```

11.0.15.4 See also:

brewer_palettes,

11.0.16 `brewer_palettes`

11.0.16.1 Possible use:

- **brewer_palettes** (int) —> list<string>
- int **brewer_palettes** int —> list<string>

- **brewer_palettes** (int , int) —> list<string>

11.0.16.2 Result:

returns the list a palette with a given min number of classes) returns the list a palette with a given min number of classes and max number of classes)

11.0.16.3 Examples:

```
list<string> var0 <- list<string> palettes <- brewer_palettes(3);; // var0 equals a list of palettes th
list<string> var1 <- list<string> palettes <- brewer_palettes(5,10);; // var1 equals a list of palettes
```

11.0.16.4 See also:

brewer_colors,

11.0.17 **buffer**

Same signification as +

11.0.18 **build**

11.0.18.1 Possible use:

- **build** (matrix<float>) —> regression
- matrix<float> **build** string —> regression
- **build** (matrix<float> , string) —> regression

11.0.18.2 Result:

returns the regression build from the matrix data (a row = an instance, the last value of each line is the y value) while using the given ordinary least squares method. Usage: build(data) returns the regression build from the matrix data (a row = an instance, the last value of each line is the y value) while using the given method ("GLS" or "OLS"). Usage: build(data,method)

11.0.18.3 Examples:

```
matrix([[1,2,3,4],[2,3,4,2]]) build(matrix([[1,2,3,4],[2,3,4,2]]),"GLS")
```

11.0.19 `ceil`

11.0.19.1 Possible use:

- `ceil` (float) —> float

11.0.19.2 Result:

Maps the operand to the smallest following integer, i.e. the smallest integer not less than x.

11.0.19.3 Examples:

```
float var0 <- ceil(3); // var0 equals 3.0
float var1 <- ceil(3.5); // var1 equals 4.0
float var2 <- ceil(-4.7); // var2 equals -4.0
```

11.0.19.4 See also:

floor, round,

11.0.20 `centroid`

11.0.20.1 Possible use:

- `centroid` (geometry) —> point

11.0.20.2 Result:

Centroid (weighted sum of the centroids of a decomposition of the area into triangles) of the operand-geometry. Can be different to the location of the geometry

11.0.20.3 Examples:

```
point var0 <- centroid(world); // var0 equals the centroid of the square, for example : {50.0,50.0}.
```

11.0.20.4 See also:

any_location_in, closest_points_with, farthest_point_to, points_at,

---

11.0.21 char

11.0.21.1 Possible use:

- **char** (int) —> string

11.0.21.2 Special cases:

- converts ACSII integer value to character

```
string var0 <- char (34); // var0 equals '"'
```

11.0.22 chi_square

11.0.22.1 Possible use:

- float **chi_square** float —> float
- **chi_square** (float , float) —> float

11.0.22.2 Result:

Returns the area under the left hand tail (from 0 to x) of the Chi square probability density function with df degrees of freedom.

11.0.23 chi_square_complemented

11.0.23.1 Possible use:

- float **chi_square_complemented** float —> float
- **chi_square_complemented** (float , float) —> float

11.0.23.2 Result:

Returns the area under the right hand tail (from x to infinity) of the Chi square probability density function with df degrees of freedom.

11.0.24 circle

11.0.24.1 Possible use:

- **circle** (float) —> geometry
- float **circle** point —> geometry
- **circle** (float , point) —> geometry

11.0.24.2 Result:

A circle geometry which radius is equal to the first operand, and the center has the location equal to the second operand. A circle geometry which radius is equal to the operand.

11.0.24.3 Comment:

the center of the circle is by default the location of the current agent in which has been called this operator.

11.0.24.4 Special cases:

- returns a point if the operand is lower or equal to 0.

- returns a point if the operand is lower or equal to 0.

11.0.24.5 Examples:

```
geometry var0 <- circle(10,{80,30}); // var0 equals a geometry as a circle of radius 10, the center wil
geometry var1 <- circle(10); // var1 equals a geometry as a circle of radius 10.
```

11.0.24.6 See also:

around, cone, line, link, norm, point, polygon, polyline, rectangle, square, triangle,

---

11.0.25 `clean`

11.0.25.1 Possible use:

- **clean** (geometry) —> geometry

11.0.25.2 Result:

A geometry corresponding to the cleaning of the operand (geometry, agent, point)

11.0.25.3 Comment:

The cleaning corresponds to a buffer with a distance of 0.0

11.0.25.4 Examples:

```
geometry var0 <- clean(self); // var0 equals returns the geometry resulting from the cleaning of the ge
```

11.0.26 `clean_network`

11.0.26.1 Possible use:

- **`clean_network`** (list<geometry>, float, bool, bool) —> list<geometry>

11.0.26.2 Result:

A list of polylines corresponding to the cleaning of the first operand (list of polyline geometry or agents), considering the tolerance distance given by the second operand; the third operator is used to define if the operator should as well split the lines at their intersections(true to split the lines); the last operandis used to specify if the operator should as well keep only the main connected component of the network. Usage: clean_network(lines:list of geometries or agents, tolerance: float, split_lines: bool, keepMainConnectedComponent: bool)

11.0.26.3 Comment:

The cleaned set of polylines

11.0.26.4 Examples:

`list<geometry> var0 <- clean_network(my_road_shapefile.contents, 1.0, true, false); // var0 equals retu`

11.0.27 `closest_points_with`

11.0.27.1 Possible use:

- geometry **`closest_points_with`** geometry —> list<point>
- **`closest_points_with`** (geometry , geometry) —> list<point>

11.0.27.2 Result:

A list of two closest points between the two geometries.

11.0.27.3 Examples:

`list<point> var0 <- geom1 closest_points_with(geom2); // var0 equals [pt1, pt2] with pt1 the closest po`

11.0.27.4 See also:

any_location_in, any_point_in, farthest_point_to, points_at,

11.0.28 `closest_to`

11.0.28.1 Possible use:

- container<agent> **closest_to** geometry —> geometry
- **closest_to** (container<agent> , geometry) —> geometry
- **closest_to** (container<agent>, geometry, int) —> list<geometry>

11.0.28.2 Result:

An agent or a geometry among the left-operand list of agents, species or meta-population (addition of species), the closest to the operand (casted as a geometry). The N agents or geometries among the left-operand list of agents, species or meta-population (addition of species), that are the closest to the operand (casted as a geometry).

11.0.28.3 Comment:

the distance is computed in the topology of the calling agent (the agent in which this operator is used), with the distance algorithm specific to the topology.the distance is computed in the topology of the calling agent (the agent in which this operator is used), with the distance algorithm specific to the topology.

11.0.28.4 Examples:

```
geometry var0 <- [ag1, ag2, ag3] closest_to(self); // var0 equals return the closest agent among ag1, ag
list<geometry> var2 <- [ag1, ag2, ag3] closest_to(self, 2); // var2 equals return the 2 closest agents a
```

11.0.28.5 See also:

neighbors_at, neighbors_of, inside, overlapping, agents_overlapping, agents_inside, agent_closest_to,

---

11.0.29 `collect`

11.0.29.1 Possible use:

- container **collect** any expression —> list
- **collect** (container , any expression) —> list

11.0.29.2 Result:

returns a new list, in which each element is the evaluation of the right-hand operand.

11.0.29.3 Comment:

collect is similar to accumulate except that accumulate always produces flat lists if the right-hand operand returns a list.In addition, collect can be applied to any container.

11.0.29.4 Special cases:

- if the left-hand operand is nil, collect throws an error

11.0.29.5 Examples:

```
list var0 <- [1,2,4] collect (each *2); // var0 equals [2,4,8]
list var1 <- [1,2,4] collect ([2,4]); // var1 equals [[2,4],[2,4],[2,4]]
list var2 <- [1::2, 3::4, 5::6] collect (each + 2); // var2 equals [4,6,8]
list var3 <- (list(node) collect (node(each).location.x * 2); // var3 equals the list of nodes with the
```

11.0.29.6 See also:

accumulate,

11.0.30 `column_at`

11.0.30.1 Possible use:

- matrix **column_at** int —> list
- **column_at** (matrix , int) —> list

11.0.30.2 Result:

returns the column at a num_col (right-hand operand)

11.0.30.3 Examples:

```
list var0 <- matrix([["el11","el12","el13"],["el21","el22","el23"],["el31","el32","el33"]]) column_at 2
```

11.0.30.4 See also:

row_at, rows_list,

11.0.31 `columns_list`

11.0.31.1 Possible use:

- **columns_list** (matrix) —> list<list>

11.0.31.2 Result:

returns a list of the columns of the matrix, with each column as a list of elements

11.0.31.3 Examples:

```
list<list> var0 <- columns_list(matrix([["el11","el12","el13"],["el21","el22","el23"],["el31","el32","el
```

11.0.31.4 See also:

rows_list,

11.0.32 `command`

11.0.32.1 Possible use:

- **command** (string) —> string
- string **command** string —> string
- **command** (string , string) —> string
- **command** (string, string, msi.gama.util.GamaMap<java.lang.String,java.lang.String>) —>
  string

11.0.32.2 Result:

command allows GAMA to issue a system command using the system terminal or shell and to receive a string containing the outcome of the command or script executed. By default, commands are blocking the agent calling them, unless the sequence '&' is used at the end. In this case, the result of the operator is an empty string command allows GAMA to issue a system command using the system terminal or shell and to receive a string containing the outcome of the command or script executed. By default, commands are blocking the agent calling them, unless the sequence '&' is used at the end. In this case, the result of the operator is an empty string. The basic form with only one string in argument uses the directory of the model and does not set any environment variables. Two other forms (with a directory and a map of environment variables) are available. command allows GAMA to issue a system command using the system terminal or shell and to receive a string containing the outcome of the command or script executed. By default, commands are blocking the agent calling them, unless the sequence '&' is used at the end. In this case, the result of the operator is an empty string. The basic form with only one string in argument uses the directory of the model and does not set any environment variables. Two other forms (with a directory and a map of environment variables) are available.

11.0.33 `cone`

11.0.33.1 Possible use:

- **cone** (point) —> geometry
- int **cone** int —> geometry
- **cone** (int , int) —> geometry

11.0.33.2 Result:

A cone geometry which min and max angles are given by the operands. A cone geometry which min and max angles are given by the operands.

11.0.33.3 Comment:

the center of the cone is by default the location of the current agent in which has been called this operator.the center of the cone is by default the location of the current agent in which has been called this operator.

11.0.33.4 Special cases:

- returns nil if the operand is nil.

- returns nil if the operand is nil.

11.0.33.5 Examples:

```
geometry var0 <- cone(0, 45); // var0 equals a geometry as a cone with min angle is 0 and max angle is 
geometry var1 <- cone({0, 45}); // var1 equals a geometry as a cone with min angle is 0 and max angle is
```

11.0.33.6 See also:

around, circle, line, link, norm, point, polygon, polyline, rectangle, square, triangle,

---

11.0.34 `cone3D`

11.0.34.1 Possible use:

- float **cone3D** float —> geometry
- **cone3D** (float , float) —> geometry

11.0.34.2 Result:

A cone geometry which base radius size is equal to the first operand, and which the height is equal to the second operand.

11.0.34.3 Comment:

the center of the cone is by default the location of the current agent in which has been called this operator.

11.0.34.4 Special cases:

- returns a point if the operand is lower or equal to 0.

11.0.34.5 Examples:

```
geometry var0 <- cone3D(10.0,5.0); // var0 equals a geometry as a cone with a base circle of radius 10 a
```

11.0.34.6 See also:

around, cone, line, link, norm, point, polygon, polyline, rectangle, square, triangle,

---

11.0.35 connected_components_of

11.0.35.1 Possible use:

- **connected_components_of** (graph) —> list<list>
- graph **connected_components_of** bool —> list<list>
- **connected_components_of** (graph , bool) —> list<list>

11.0.35.2 Result:

returns the connected components of a graph, i.e. the list of all vertices that are in the maximally connected
component together with the specified vertex. returns the connected components of a graph, i.e. the list of
all edges (if the boolean is true) or vertices (if the boolean is false) that are in the connected components.

11.0.35.3 Examples:

```
graph my_graph <- graph([]);
list<list> var1 <- connected_components_of (my_graph); // var1 equals the list of all the components as
list<list> var3 <- connected_components_of (my_graph2, true); // var3 equals the list of all the compone
```

11.0.35.4 See also:

alpha_index, connectivity_index, nb_cycles,

11.0.36 connectivity_index

11.0.36.1 Possible use:

- **connectivity_index** (graph) —> float

11.0.36.2 Result:

returns a simple connectivity index. This number is estimated through the number of nodes (v) and of
sub-graphs (p) : IC = (v - p) /(v - 1).

11.0.36.3 Examples:

```
graph graphEpidemio <- graph([]);
float var1 <- connectivity_index(graphEpidemio); // var1 equals the connectivity index of the graph
```

11.0.36.4 See also:

alpha_index, beta_index, gamma_index, nb_cycles,

11.0.37 container

11.0.37.1 Possible use:

- **container** (any) —> container

11.0.37.2 Result:

Casts the operand into the type container

11.0.38 contains

11.0.38.1 Possible use:

- container<KeyType,ValueType> **contains** unknown —> bool
- **contains** (container<KeyType,ValueType> , unknown) —> bool
- string **contains** string —> bool
- **contains** (string , string) —> bool

11.0.38.2 Result:

true, if the container contains the right operand, false otherwise

11.0.38.3 Comment:

the contains operator behavior depends on the nature of the operand

11.0.38.4 Special cases:

- if it is a map, contains returns true if the operand is a key of the map

- if it is a file, contains returns true it the operand is contained in the file content

- if it is a population, contains returns true if the operand is an agent of the population, false otherwise

- if it is a graph, contains returns true if the operand is a node or an edge of the graph, false otherwise

- if both operands are strings, returns true if the right-hand operand contains the right-hand pattern;

- if it is a list or a matrix, contains returns true if the list or matrix contains the right operand

```
bool var0 <- [1, 2, 3] contains 2; // var0 equals true
bool var1 <- [{1,2}, {3,4}, {5,6}] contains {3,4}; // var1 equals true
```

11.0.38.5 Examples:

```
bool var2 <- 'abcded' contains 'bc'; // var2 equals true
```

11.0.38.6 See also:

contains_all, contains_any,

11.0.39 `contains_all`

11.0.39.1 Possible use:

- string **contains_all** list —> bool
- **contains_all** (string , list) —> bool
- container **contains_all** container —> bool
- **contains_all** (container , container) —> bool

11.0.39.2 Result:

true if the left operand contains all the elements of the right operand, false otherwise

11.0.39.3 Comment:

the definition of contains depends on the container

11.0.39.4 Special cases:

- if the right operand is nil or empty, contains_all returns true

- if the left-operand is a string, test whether the string contains all the element of the list;

```
bool var0 <- "abcabcabc" contains_all ["ca","xy"]; // var0 equals false
```

11.0.39.5 Examples:

```
bool var1 <- [1,2,3,4,5,6] contains_all [2,4]; // var1 equals true
bool var2 <- [1,2,3,4,5,6] contains_all [2,8]; // var2 equals false
bool var3 <- [1::2, 3::4, 5::6] contains_all [1,3]; // var3 equals false
bool var4 <- [1::2, 3::4, 5::6] contains_all [2,4]; // var4 equals true
```

11.0.39.6 See also:

contains, contains_any,

11.0.40 `contains_any`

11.0.40.1 Possible use:

- string **contains_any** list —> bool
- **contains_any** (string , list) —> bool
- container **contains_any** container —> bool
- **contains_any** (container , container) —> bool

11.0.40.2 Result:

true if the left operand contains one of the elements of the right operand, false otherwise

11.0.40.3 Comment:

the definition of contains depends on the container

11.0.40.4 Special cases:

- if the right operand is nil or empty, contains_any returns false

11.0.40.5 Examples:

```
bool var0 <- "abcabcabc" contains_any ["ca","xy"]; // var0 equals true
bool var1 <- [1,2,3,4,5,6] contains_any [2,4]; // var1 equals true
bool var2 <- [1,2,3,4,5,6] contains_any [2,8]; // var2 equals true
bool var3 <- [1::2, 3::4, 5::6] contains_any [1,3]; // var3 equals false
bool var4 <- [1::2, 3::4, 5::6] contains_any [2,4]; // var4 equals true
```

11.0.40.6 See also:

contains, contains_all,

11.0.41 `contains_edge`

11.0.41.1 Possible use:

- graph **contains_edge** unknown —> bool
- **contains_edge** (graph , unknown) —> bool
- graph **contains_edge** pair —> bool
- **contains_edge** (graph , pair) —> bool

11.0.41.2 Result:

returns true if the graph(left-hand operand) contains the given edge (righ-hand operand), false otherwise

11.0.41.3 Special cases:

- if the left-hand operand is nil, returns false

- if the right-hand operand is a pair, returns true if it exists an edge between the two elements of the pair in the graph

```
bool var2 <- graphEpidemio contains_edge (node(0)::node(3)); // var2 equals true
```

11.0.41.4 Examples:

```
graph graphFromMap <-  as_edge_graph([{1,5}::{12,45},{12,45}::{34,56}]);
bool var1 <- graphFromMap contains_edge link({1,5},{12,45}); // var1 equals true
```

11.0.41.5 See also:

contains_vertex,

11.0.42 `contains_vertex`

11.0.42.1 Possible use:

- graph **contains_vertex** unknown —> bool
- **contains_vertex** (graph , unknown) —> bool

11.0.42.2 Result:

returns true if the graph(left-hand operand) contains the given vertex (righ-hand operand), false otherwise

11.0.42.3 Special cases:

- if the left-hand operand is nil, returns false

11.0.42.4 Examples:

```
graph graphFromMap<-  as_edge_graph([{1,5}::{12,45},{12,45}::{34,56}]);
bool var1 <- graphFromMap contains_vertex {1,5}; // var1 equals true
```

11.0.42.5 See also:

contains_edge,

11.0.43 conversation

11.0.43.1 Possible use:

- **conversation** (unknown) —> conversation

11.0.44 convex_hull

11.0.44.1 Possible use:

- **convex_hull** (geometry) —> geometry

11.0.44.2 Result:

A geometry corresponding to the convex hull of the operand.

11.0.44.3 Examples:

```
geometry var0 <- convex_hull(self); // var0 equals the convex hull of the geometry of the agent applying
```

11.0.45 copy

11.0.45.1 Possible use:

- **copy** (unknown) —> unknown

11.0.45.2 Result:

returns a copy of the operand.

11.0.46 `copy_between`

11.0.46.1 Possible use:

- `copy_between` (string, int, int) —> `string`
- `copy_between` (list, int, int) —> `list`

11.0.46.2 Result:

Returns a copy of the first operand between the indexes determined by the second (inclusive) and third operands (exclusive)

11.0.46.3 Special cases:

- If the first operand is empty, returns an empty object of the same type

- If the second operand is greater than or equal to the third operand, return an empty object of the same type

- If the first operand is nil, raises an error

11.0.46.4 Examples:

```
string var0 <- copy_between("abcabcabc", 2,6); // var0 equals "cabc"
list var1 <-  copy_between ([4, 1, 6, 9 ,7], 1, 3); // var1 equals [1, 6]
```

11.0.47 `corR`

11.0.47.1 Possible use:

- `container` **`corR`** `container` —> `unknown`
- **`corR`** (container , container) —> `unknown`

11.0.47.2 Result:

returns the Pearson correlation coefficient of two given vectors (right-hand operands) in given variable (left-hand operand).

11.0.47.3 Special cases:

- if the lengths of two vectors in the right-hand aren't equal, returns 0

11.0.47.4 Examples:

```
list X <- [1, 2, 3]; list Y <- [1, 2, 4];
unknown var2 <- corR(X, Y); // var2 equals 0.981980506061966
```

11.0.48 correlation

11.0.48.1 Possible use:

- container **correlation** container —> float
- **correlation** (container , container) —> float

11.0.48.2 Result:

Returns the correlation of two data sequences

11.0.49 cos

11.0.49.1 Possible use:

- **cos** (int) —> float
- **cos** (float) —> float

11.0.49.2 Result:

Returns the value (in [-1,1]) of the cosinus of the operand (in decimal degrees). The argument is casted to an int before being evaluated.

11.0.49.3 Special cases:

- Operand values out of the range [0-359] are normalized.

11.0.49.4 Examples:

```
float var0 <- cos (0); // var0 equals 1.0
float var1 <- cos(360); // var1 equals 1.0
float var2 <- cos(-720); // var2 equals 1.0
```

11.0.49.5 See also:

sin, tan,

11.0.50 `cos_rad`

11.0.50.1 Possible use:

- **`cos_rad`** (float) —> float

11.0.50.2 Result:

Returns the value (in [-1,1]) of the cosinus of the operand (in radians).

11.0.50.3 Special cases:

- Operand values out of the range [0-359] are normalized.

11.0.50.4 See also:

sin, tan,

11.0.51 `count`

11.0.51.1 Possible use:

- container **count** any expression —> int
- **count** (container , any expression) —> int

11.0.51.2 Result:

returns an int, equal to the number of elements of the left-hand operand that make the right-hand operand evaluate to true.

11.0.51.3 Comment:

in the right-hand operand, the keyword each can be used to represent, in turn, each of the elements.

11.0.51.4 Special cases:

- if the left-hand operand is nil, count throws an error

11.0.51.5 Examples:

```
int var0 <- [1,2,3,4,5,6,7,8] count (each > 3); // var0 equals 5// Number of nodes of graph g2 without a
int var3 <- g2 count (length(g2 out_edges_of each) = 0  ) ; // var3 equals the total number of out edges
int var6 <- [1::2, 3::4, 5::6] count (each > 4); // var6 equals 1
```

11.0.51.6   See also:

group_by,

11.0.52   `covariance`

11.0.52.1   Possible use:

- container **covariance** container —> float
- **covariance** (container , container) —> float

11.0.52.2   Result:

Returns the covariance of two data sequences

11.0.53   `covers`

11.0.53.1   Possible use:

- geometry **covers** geometry —> bool
- **covers** (geometry , geometry) —> bool

11.0.53.2   Result:

A boolean, equal to true if the left-geometry (or agent/point) covers the right-geometry (or agent/point).

11.0.53.3   Special cases:

- if one of the operand is null, returns false.

11.0.53.4   Examples:

bool var0 <- square(5) covers square(2); // var0 equals true

11.0.53.5   See also:

disjoint_from, crosses, overlaps, partially_overlaps, touches,

---

11.0.54 create_map

11.0.54.1 Possible use:

- list **create_map** list —> map
- **create_map** (list , list) —> map

11.0.54.2 Result:

returns a new map using the left operand as keys for the right operand

11.0.54.3 Special cases:

- if the left operand contains duplicates, create_map throws an error.

- if both operands have different lengths, choose the minimum length between the two operandsfor the size of the map

11.0.54.4 Examples:

```
map<int,string> var0 <- create_map([0,1,2],['a','b','c']); // var0 equals [0::'a',1::'b',2::'c']
map<int,float> var1 <- create_map([0,1],[0.1,0.2,0.3]); // var1 equals [0::0.1,1::0.2]
map<string,float> var2 <- create_map(['a','b','c','d'],[1.0,2.0,3.0]); // var2 equals ['a'::1.0,'b'::2.0
```

11.0.55 cross

11.0.55.1 Possible use:

- **cross** (float) —> geometry
- float **cross** float —> geometry
- **cross** (float , float) —> geometry

11.0.55.2 Result:

A cross, which radius is equal to the first operand A cross, which radius is equal to the first operand and the width of the lines for the second

11.0.55.3 Examples:

```
geometry var0 <- cross(10); // var0 equals a geometry as a cross of radius 10
geometry var1 <- cross(10,2); // var1 equals a geometry as a cross of radius 10, and with a width of 2
```

11.0.55.4   See also:

around, cone, line, link, norm, point, polygon, polyline, super_ellipse, rectangle, square, circle, ellipse, triangle,

---

11.0.56   `crosses`

11.0.56.1   Possible use:

- geometry **crosses** geometry —> `bool`
- **crosses** (geometry , geometry) —> `bool`

11.0.56.2   Result:

A boolean, equal to true if the left-geometry (or agent/point) crosses the right-geometry (or agent/point).

11.0.56.3   Special cases:

- if one of the operand is null, returns false.

- if one operand is a point, returns false.

11.0.56.4   Examples:

```
bool var0 <- polyline([{10,10},{20,20}]) crosses polyline([{10,20},{20,10}]); // var0 equals true
bool var1 <- polyline([{10,10},{20,20}]) crosses {15,15}; // var1 equals true
bool var2 <- polyline([{0,0},{25,25}]) crosses polygon([{10,10},{10,20},{20,20},{20,10}]); // var2 equal
```

11.0.56.5   See also:

disjoint_from, intersects, overlaps, partially_overlaps, touches,

---

11.0.57   `crs`

11.0.57.1   Possible use:

- **crs** (file) —> `string`

11.0.57.2   Result:

the Coordinate Reference System (CRS) of the GIS file

11.0.57.3 Examples:

```
string var0 <- crs(my_shapefile); // var0 equals the crs of the shapefile
```

11.0.58 CRS_transform

11.0.58.1 Possible use:

- **CRS_transform** (geometry) —> geometry
- geometry **CRS_transform** string —> geometry
- **CRS_transform** (geometry , string) —> geometry

11.0.58.2 Special cases:

- returns the geometry corresponding to the transformation of the given geometry by the left operand CRS (Coordinate Reference System)

```
geometry var0 <- shape CRS_transform("EPSG:4326"); // var0 equals a geometry corresponding to the agent
```

- returns the geometry corresponding to the transformation of the given geometry by the current CRS (Coordinate Reference System), the one corresponding to the world's agent one

```
geometry var1 <- CRS_transform(shape); // var1 equals a geometry corresponding to the agent geometry tra
```

11.0.59 csv_file

11.0.59.1 Possible use:

- **csv_file** (string) —> file

11.0.59.2 Result:

Constructs a file of type csv. Allowed extensions are limited to csv, tsv

---

11.0.60 cube

11.0.60.1 Possible use:

- **cube** (float) —> geometry

11.0.60.2 Result:

A cube geometry which side size is equal to the operand.

11.0.60.3   Comment:

the center of the cube is by default the location of the current agent in which has been called this operator.

11.0.60.4   Special cases:

- returns nil if the operand is nil.

11.0.60.5   Examples:

```
geometry var0 <- cube(10); // var0 equals a geometry as a square of side size 10.
```

11.0.60.6   See also:

around, circle, cone, line, link, norm, point, polygon, polyline, rectangle, triangle,

---

11.0.61   curve

11.0.61.1   Possible use:

- **curve** (point, point, point) —> geometry
- **curve** (point, point, float) —> geometry
- **curve** (point, point, point, int) —> geometry
- **curve** (point, point, float, float) —> geometry
- **curve** (point, point, float, bool) —> geometry
- **curve** (point, point, point, point) —> geometry
- **curve** (point, point, float, bool, int) —> geometry
- **curve** (point, point, point, point, int) —> geometry
- **curve** (point, point, float, int, float) —> geometry
- **curve** (point, point, float, int, float, float) —> geometry
- **curve** (point, point, float, bool, int, float) —> geometry

11.0.61.2   Result:

A cubic Bezier curve geometry built from the two given points with the given coefficient for the radius and composed of the given number of points, considering the given inflection point (between 0.0 and 1.0 - default 0.5), and the given rotation angle (90 = along the z axis). A quadratic Bezier curve geometry built from the three given points composed of a given numnber of points. A cubic Bezier curve geometry built from the two given points with the given coefficient for the radius considering the given rotation angle (90 = along the z axis). A cubic Bezier curve geometry built from the two given points with the given coefficient for the radius and composed of the given number of points - the boolean is used to specified if it is the right side. A quadratic Bezier curve geometry built from the three given points composed of 10 points. A cubic Bezier curve geometry built from the four given points composed of a given number of points. A cubic Bezier curve geometry built from the two given points with the given coefficient for the radius and composed of the given number of points, considering the given rotation angle (90 = along the z axis). A cubic Bezier curve geometry built from the two given points with the given coefficient for the radius and composed of 10 points - the last boolean is used to specified if it is the right side. A cubic Bezier curve geometry built from the two given points with the given coefficient for the radius and composed of the given number of points - the

boolean is used to specified if it is the right side and the last value to indicate where is the inflection point (between 0.0 and 1.0 - default 0.5). A cubic Bezier curve geometry built from the two given points with the given coefficient for the radius and composed of 10 points. A cubic Bezier curve geometry built from the four given points composed of 10 points.

11.0.61.3 Special cases:

- if the operand is nil, returns nil

- if the operand is nil, returns nil

- if the last operand (number of points) is inferior to 2, returns nil

- if the operand is nil, returns nil

- if the operand is nil, returns nil

- if the operand is nil, returns nil

- if the operand is nil, returns nil

- if the last operand (number of points) is inferior to 2, returns nil

- if the operand is nil, returns nil

- if the operand is nil, returns nil

- if the operand is nil, returns nil

- if the operand is nil, returns nil

- if the operand is nil, returns nil

11.0.61.4 Examples:

```
geometry var0 <- curve({0,0},{10,10}, 0.5, 100, 0.8, 90); // var0 equals a cubic Bezier curve geometry
geometry var1 <- curve({0,0}, {0,10}, {10,10}, 20); // var1 equals a quadratic Bezier curve geometry con
geometry var2 <- curve({0,0},{10,10}, 0.5, 90); // var2 equals a cubic Bezier curve geometry composed or
geometry var3 <- curve({0,0},{10,10}, 0.5, false, 100); // var3 equals a cubic Bezier curve geometry con
geometry var4 <- curve({0,0}, {0,10}, {10,10}); // var4 equals a quadratic Bezier curve geometry compose
geometry var5 <- curve({0,0}, {0,10}, {10,10}); // var5 equals a cubic Bezier curve geometry composed or
geometry var6 <- curve({0,0},{10,10}, 0.5, 100, 90); // var6 equals a cubic Bezier curve geometry compos
geometry var7 <- curve({0,0},{10,10}, 0.5, false); // var7 equals a cubic Bezier curve geometry composed
geometry var8 <- curve({0,0},{10,10}, 0.5, false, 100, 0.8); // var8 equals a cubic Bezier curve geometr
geometry var9 <- curve({0,0},{10,10}, 0.5); // var9 equals a cubic Bezier curve geometry composed of 10
geometry var10 <- curve({0,0}, {0,10}, {10,10}); // var10 equals a cubic Bezier curve geometry composed
```

11.0.61.5 See also:

around, circle, cone, link, norm, point, polygone, rectangle, square, triangle, line,

11.0.62 `cylinder`

11.0.62.1 Possible use:

- float **cylinder** float —> geometry
- **cylinder** (float , float) —> geometry

11.0.62.2 Result:

A cylinder geometry which radius is equal to the operand.

11.0.62.3 Comment:

the center of the cylinder is by default the location of the current agent in which has been called this operator.

11.0.62.4 Special cases:

- returns a point if the operand is lower or equal to 0.

11.0.62.5 Examples:

```
geometry var0 <- cylinder(10,10); // var0 equals a geometry as a circle of radius 10.
```

11.0.62.6 See also:

around, cone, line, link, norm, point, polygon, polyline, rectangle, square, triangle,

Chapter 12

Operators (D to H)

12.0.1 `date`

12.0.1.1 Possible use:

- `string` **`date`** `string` —> `date`
- **`date`** `(string , string)` —> `date`
- **`date`** `(string, string, string)` —> `date`

12.0.1.2 Result:

converts a string to a date following a custom pattern and a specific locale (e.g. 'fr', 'en'...). The pattern can use "%Y %M %N %D %E %h %m %s %z" for parsing years, months, name of month, days, name of days, hours, minutes, seconds and the time-zone. A null or empty pattern will parse the date using one of the ISO date & time formats (similar to date('...') in that case). The pattern can also follow the pattern definition found here, which gives much more control over what will be parsed: https://docs.oracle.com/javase/8/docs/api/java/time/format/DateTimeFormatter.html#patterns. Different patterns are available by default as constant: #iso_local, #iso_simple, #iso_offset, #iso_zoned and #custom, which can be changed in the preferences converts a string to a date following a custom pattern. The pattern can use "%Y %M %N %D %E %h %m %s %z" for outputting years, months, name of month, days, name of days, hours, minutes, seconds and the time-zone. A null or empty pattern will parse the date using one of the ISO date & time formats (similar to date('...') in that case). The pattern can also follow the pattern definition found here, which gives much more control over what will be parsed: https://docs.oracle.com/javase/8/docs/api/java/time/format/DateTimeFormatter.html#patterns. Different patterns are available by default as constant: #iso_local, #iso_simple, #iso_offset, #iso_zoned and #custom, which can be changed in the preferences

12.0.1.3 Examples:

`date d <- date("1999-january-30", 'yyyy-MMMM-dd', 'en'); date den <- date("1999-12-30", 'yyyy-MM-dd');`

12.0.2 dbscan

12.0.2.1 Possible use:

- **dbscan** (list, float, int) —> list<list>

12.0.2.2 Result:

returns the list of clusters (list of instance indices) computed with the dbscan (density-based spatial clustering of applications with noise) algorithm from the first operand data according to the maximum radius of the neighborhood to be considered (eps) and the minimum number of points needed for a cluster (minPts). Usage: dbscan(data,eps,minPoints)

12.0.2.3 Special cases:

- if the lengths of two vectors in the right-hand aren't equal, returns 0

12.0.2.4 Examples:

list<list> var0 <- dbscan ([[2,4,5], [3,8,2], [1,1,3], [4,3,4]],10,2); // var0 equals []

12.0.3 dead

12.0.3.1 Possible use:

- **dead** (agent) —> bool

12.0.3.2 Result:

true if the agent is dead (or null), false otherwise.

12.0.3.3 Examples:

bool var0 <- dead(agent_A); // var0 equals true or false

12.0.4 degree_of

12.0.4.1 Possible use:

- graph **degree_of** unknown —> int
- **degree_of** (graph , unknown) —> int

12.0.4.2 Result:

returns the degree (in+out) of a vertex (right-hand operand) in the graph given as left-hand operand.

12.0.4.3 Examples:

```
int var1 <- graphFromMap degree_of (node(3)); // var1 equals 3
```

12.0.4.4 See also:

in_degree_of, out_degree_of,

12.0.5 `dem`

12.0.5.1 Possible use:

- **dem** (file) —> geometry
- file **dem** file —> geometry
- **dem** (file , file) —> geometry
- file **dem** float —> geometry
- **dem** (file , float) —> geometry
- **dem** (file, file, float) —> geometry

12.0.5.2 Result:

A polygon that is equivalent to the surface of the texture

12.0.5.3 Examples:

```
geometry var0 <- dem(dem); // var0 equals returns a geometry as a rectangle of width and height equal t
geometry var1 <- dem(dem,texture); // var1 equals a geometry as a rectangle of weight and height equal
geometry var2 <- dem(dem,z_factor); // var2 equals a geometry as a rectangle of weight and height equal
geometry var3 <- dem(dem,texture,z_factor); // var3 equals a geometry as a rectangle of width and heigh
```

12.0.6 `det`

Same signification as determinant

12.0.7 `determinant`

12.0.7.1 Possible use:

- `determinant` (matrix) —> `float`

12.0.7.2 Result:

The determinant of the given matrix

12.0.7.3 Examples:

```
float var0 <- determinant(matrix([[1,2],[3,4]])); // var0 equals -2
```

12.0.8 `diff`

12.0.8.1 Possible use:

- `float` **diff** `float` —> `float`
- **diff** (`float` , `float`) —> `float`

12.0.8.2 Result:

A placeholder function for expressing equations

12.0.9 `diff2`

12.0.9.1 Possible use:

- `float` **diff2** `float` —> `float`
- **diff2** (`float` , `float`) —> `float`

12.0.9.2 Result:

A placeholder function for expressing equations

12.0.10 `directed`

12.0.10.1 Possible use:

- `directed` (graph) —> `graph`

12.0.10.2 Result:

the operand graph becomes a directed graph.

12.0.10.3 Comment:

the operator alters the operand graph, it does not create a new one.

12.0.10.4 See also:

undirected,

12.0.11 `direction_between`

12.0.11.1 Possible use:

- topology **direction_between** container<geometry> —> float
- **direction_between** (topology , container<geometry>) —> float

12.0.11.2 Result:

A direction (in degree) between a list of two geometries (geometries, agents, points) considering a topology.

12.0.11.3 Examples:

```
float var0 <- my_topology direction_between [ag1, ag2]; // var0 equals the direction between ag1 and ag2
```

12.0.11.4 See also:

towards, direction_to, distance_to, distance_between, path_between, path_to,

---

12.0.12 `direction_to`

Same signification as towards

12.0.13 `disjoint_from`

12.0.13.1 Possible use:

- geometry **disjoint_from** geometry —> bool
- **disjoint_from** (geometry , geometry) —> bool

12.0.13.2 Result:

A boolean, equal to true if the left-geometry (or agent/point) is disjoints from the right-geometry (or agent/point).

12.0.13.3 Special cases:

- if one of the operand is null, returns true.

- if one operand is a point, returns false if the point is included in the geometry.

12.0.13.4 Examples:

```
bool var0 <- polyline([{10,10},{20,20}]) disjoint_from polyline([{15,15},{25,25}]); // var0 equals false
bool var1 <- polygon([{10,10},{10,20},{20,20},{20,10}]) disjoint_from polygon([{15,15},{15,25},{25,25},
bool var2 <- polygon([{10,10},{10,20},{20,20},{20,10}]) disjoint_from {15,15}; // var2 equals false
bool var3 <- polygon([{10,10},{10,20},{20,20},{20,10}]) disjoint_from {25,25}; // var3 equals true
bool var4 <- polygon([{10,10},{10,20},{20,20},{20,10}]) disjoint_from polygon([{35,35},{35,45},{45,45},
```

12.0.13.5 See also:

intersects, crosses, overlaps, partially_overlaps, touches,

12.0.14 `distance_between`

12.0.14.1 Possible use:

- topology **distance_between** container<geometry> —> float
- **distance_between** (topology , container<geometry>) —> float

12.0.14.2 Result:

A distance between a list of geometries (geometries, agents, points) considering a topology.

12.0.14.3 Examples:

```
float var0 <- my_topology distance_between [ag1, ag2, ag3]; // var0 equals the distance between ag1, ag2
```

12.0.14.4 See also:

towards, direction_to, distance_to, direction_between, path_between, path_to,

---

12.0.15 `distance_to`

12.0.15.1 Possible use:

- point **distance_to** point —> float
- **distance_to** (point , point) —> float
- geometry **distance_to** geometry —> float
- **distance_to** (geometry , geometry) —> float

12.0.15.2 Result:

A distance between two geometries (geometries, agents or points) considering the topology of the agent applying the operator.

12.0.15.3 Examples:

```
float var0 <- ag1 distance_to ag2; // var0 equals the distance between ag1 and ag2 considering the topol
```

12.0.15.4 See also:

towards, direction_to, distance_between, direction_between, path_between, path_to,

---

12.0.16 `distinct`

12.0.16.1 Possible use:

- **distinct** (container) —> list

12.0.16.2 Result:

produces a set from the elements of the operand (i.e. a list without duplicated elements)

12.0.16.3 Special cases:

- if the operand is nil, remove_duplicates returns nil

- if the operand is a graph, remove_duplicates returns the set of nodes

- if the operand is a matrix, remove_duplicates returns a matrix without duplicated row

- if the operand is a map, remove_duplicates returns the set of values without duplicate

```
list var1 <- remove_duplicates([1::3,2::4,3::3,5::7]); // var1 equals [3,4,7]
```

12.0.16.4   Examples:

```
list var0 <- remove_duplicates([3,2,5,1,2,3,5,5,5]); // var0 equals [3,2,5,1]
```

12.0.17   `distribution_of`

12.0.17.1   Possible use:

- **distribution_of** (container) —> map
- container **distribution_of** int —> map
- **distribution_of** (container , int) —> map
- **distribution_of** (container, int, float, float) —> map

12.0.17.2   Result:

Discretize a list of values into n bins (computes the bins from a numerical variable into n (default 10) bins. Returns a distribution map with the values (values key), the interval legends (legend key), the distribution parameters (params keys, for cumulative charts). Parameters can be (list), (list, nbbins) or (list,nbbins,valmin,valmax)

12.0.17.3   Examples:

```
map var0 <- distribution_of([1,1,2,12.5],10); // var0 equals map(['values'::[2,1,0,0,0,0,1,0,0,0],'leger
map var1 <- distribution_of([1,1,2,12.5]); // var1 equals map(['values'::[2,1,0,0,0,0,1,0,0,0],'legend'
map var2 <- distribution_of([1,1,2,12.5]); // var2 equals map(['values'::[2,1,0,0,0,0,1,0,0,0],'legend'
```

12.0.17.4   See also:

as_map,

12.0.18   `distribution2d_of`

12.0.18.1   Possible use:

- container **distribution2d_of** container —> map
- **distribution2d_of** (container , container) —> map
- **distribution2d_of** (container, container, int, int) —> map
- **distribution2d_of** (container, container, int, float, float, int, float, float) —> map

12.0.18.2   Result:

Discretize two lists of values into n bins (computes the bins from a numerical variable into n (default 10) bins. Returns a distribution map with the values (values key), the interval legends (legend key), the distribution parameters (params keys, for cumulative charts). Parameters can be (list), (list, nbbins) or (list,nbbins,valmin,valmax)

12.0.18.3 Examples:

```
map var0 <- distribution2d_of([1,1,2,12.5]); // var0 equals map(['values'::[2,1,0,0,0,0,1,0,0,0],'legend
map var1 <- distribution_of([1,1,2,12.5],10); // var1 equals map(['values'::[2,1,0,0,0,0,1,0,0,0],'legen
map var2 <- distribution_of([1,1,2,12.5],10); // var2 equals map(['values'::[2,1,0,0,0,0,1,0,0,0],'legen
```

12.0.18.4 See also:

as_map,

12.0.19 `div`

12.0.19.1 Possible use:

- int **div** int —> int
- **div** (int , int) —> int
- float **div** int —> int
- **div** (float , int) —> int
- float **div** float —> int
- **div** (float , float) —> int
- int **div** float —> int
- **div** (int , float) —> int

12.0.19.2 Result:

Returns the truncation of the division of the left-hand operand by the right-hand operand.

12.0.19.3 Special cases:

- if the right-hand operand is equal to zero, raises an exception.

- if the right-hand operand is equal to zero, raises an exception.

- if the right-hand operand is equal to zero, raises an exception.

12.0.19.4 Examples:

```
int var0 <- 40 div 3; // var0 equals 13
int var1 <- 40.5 div 3; // var1 equals 13
int var2 <- 40.1 div 4.5; // var2 equals 8
int var3 <- 40 div 4.1; // var3 equals 9
```

12.0.19.5 See also:

mod,

12.0.20 dnorm

Same signification as normal_density

12.0.21 dtw

12.0.21.1 Possible use:

- list **dtw** list —> float
- **dtw** (list , list) —> float
- **dtw** (list, list, int) —> float

12.0.21.2 Result:

returns the dynamic time warping between the two series of value with Sakoe-Chiba band (radius: the window width of Sakoe-Chiba band) returns the dynamic time warping between the two series of value

12.0.21.3 Examples:

```
float var0 <- dtw([10.0,5.0,1.0, 3.0],[1.0,10.0,5.0,1.0], 2); // var0 equals 2.0
float var1 <- dtw([10.0,5.0,1.0, 3.0],[1.0,10.0,5.0,1.0]); // var1 equals 2
```

12.0.22 durbin_watson

12.0.22.1 Possible use:

- **durbin_watson** (container) —> float

12.0.22.2 Result:

Durbin-Watson computation

12.0.23 dxf_file

12.0.23.1 Possible use:

- **dxf_file** (string) —> file

12.0.23.2 Result:

Constructs a file of type dxf. Allowed extensions are limited to dxf

---

12.0.24 `edge`

12.0.24.1 Possible use:

- **edge** (pair) —> unknown
- **edge** (unknown) —> unknown
- unknown **edge** float —> unknown
- **edge** (unknown , float) —> unknown
- pair **edge** float —> unknown
- **edge** (pair , float) —> unknown
- unknown **edge** unknown —> unknown
- **edge** (unknown , unknown) —> unknown
- **edge** (unknown, unknown, unknown) —> unknown
- **edge** (unknown, unknown, float) —> unknown
- **edge** (pair, unknown, float) —> unknown
- **edge** (unknown, unknown, unknown, float) —> unknown

12.0.25 `edge_between`

12.0.25.1 Possible use:

- graph **edge_between** pair —> unknown
- **edge_between** (graph , pair) —> unknown

12.0.25.2 Result:

returns the edge linking two nodes

12.0.25.3 Examples:

```
unknown var0 <- graphFromMap edge_between node1::node2; // var0 equals edge1
```

12.0.25.4 See also:

out_edges_of, in_edges_of,

12.0.26 `edge_betweenness`

12.0.26.1 Possible use:

- **edge_betweenness** (graph) —> map

12.0.26.2 Result:

returns a map containing for each edge (key), its betweenness centrality (value): number of shortest paths passing through each edge

12.0.26.3 Examples:

```
graph graphEpidemio <- graph([]);
map var1 <- edge_betweenness(graphEpidemio); // var1 equals the edge betweenness index of the graph
```

12.0.27 edges

12.0.27.1 Possible use:

- **edges** (container) —> container

12.0.28 eigenvalues

12.0.28.1 Possible use:

- **eigenvalues** (matrix) —> list<float>

12.0.28.2 Result:

The eigen values (matrix) of the given matrix

12.0.28.3 Examples:

```
list<float> var0 <- eigenvalues(matrix([[5,-3],[6,-4]])); // var0 equals [2.0000000000000004,-0.99999999
```

12.0.29 electre_DM

12.0.29.1 Possible use:

- **electre_DM** (msi.gama.util.IList<java.util.List>, msi.gama.util.IList<java.util.Map<java.lang.String,
  float) —> int

12.0.29.2 Result:

The index of the best candidate according to a method based on the ELECTRE methods. The principle of the ELECTRE methods is to compare the possible candidates by pair. These methods analyses the possible outranking relation existing between two candidates. An candidate outranks another if this one is at least as good as the other one. The ELECTRE methods are based on two concepts: the concordance and the discordance. The concordance characterizes the fact that, for an outranking relation to be validated, a sufficient majority of criteria should be in favor of this assertion. The discordance characterizes the fact that, for an outranking relation to be validated, none of the criteria in the minority should oppose too strongly this assertion. These two conditions must be true for validating the outranking assertion. More information about the ELECTRE methods can be found in [http://www.springerlink.com/content/g367r44322876223/ Figueira, J., Mousseau, V., Roy, B.: ELECTRE Methods. In: Figueira, J., Greco, S., and Ehrgott, M.,

(Eds.), Multiple Criteria Decision Analysis: State of the Art Surveys, Springer, New York, 133–162 (2005)]. The first operand is the list of candidates (a candidate is a list of criterion values); the second operand the list of criterion: A criterion is a map that contains fives elements: a name, a weight, a preference value (p), an indifference value (q) and a veto value (v). The preference value represents the threshold from which the difference between two criterion values allows to prefer one vector of values over another. The indifference value represents the threshold from which the difference between two criterion values is considered significant. The veto value represents the threshold from which the difference between two criterion values disqualifies the candidate that obtained the smaller value; the last operand is the fuzzy cut.

12.0.29.3 Special cases:

- returns -1 is the list of candidates is nil or empty

12.0.29.4 Examples:

```
int var0 <- electre_DM([[1.0, 7.0],[4.0,2.0],[3.0, 3.0]], [["name"::"utility", "weight" :: 2.0,"p"::0.5
```

12.0.29.5 See also:

weighted_means_DM, promethee_DM, evidence_theory_DM,

12.0.30 `ellipse`

12.0.30.1 Possible use:

- float **ellipse** float —> geometry
- **ellipse** (float , float) —> geometry

12.0.30.2 Result:

An ellipse geometry which x-radius is equal to the first operand and y-radius is equal to the second operand

12.0.30.3 Comment:

the center of the ellipse is by default the location of the current agent in which has been called this operator.

12.0.30.4 Special cases:

- returns a point if both operands are lower or equal to 0, a line if only one is.

12.0.30.5 Examples:

```
geometry var0 <- ellipse(10, 10); // var0 equals a geometry as an ellipse of width 10 and height 10.
```

12.0.30.6   See also:

around, cone, line, link, norm, point, polygon, polyline, rectangle, square, circle, squircle, triangle,

---

12.0.31   `emotion`

12.0.31.1   Possible use:

- `emotion` (any) —> `emotion`

12.0.31.2   Result:

Casts the operand into the type emotion

12.0.32   `empty`

12.0.32.1   Possible use:

- `empty` (string) —> `bool`
- `empty` (container<KeyType,ValueType>) —> `bool`

12.0.32.2   Result:

true if the operand is empty, false otherwise.

12.0.32.3   Comment:

the empty operator behavior depends on the nature of the operand

12.0.32.4   Special cases:

- if it is a map, empty returns true if the map contains no key-value mappings, and false otherwise

- if it is a file, empty returns true if the content of the file (that is also a container) is empty, and false otherwise

- if it is a population, empty returns true if there is no agent in the population, and false otherwise

- if it is a graph, empty returns true if it contains no vertex and no edge, and false otherwise

- if it is a matrix of int, float or object, it will return true if all elements are respectively 0, 0.0 or null, and false otherwise

- if it is a matrix of geometry, it will return true if the matrix contains no cell, and false otherwise

- if it is a string, empty returns true if the string does not contain any character, and false otherwise

```
bool var0 <- empty ('abced'); // var0 equals false
```

- if it is a list, empty returns true if there is no element in the list, and false otherwise

```
bool var1 <- empty([]); // var1 equals true
```

12.0.33 enlarged_by

Same signification as +

12.0.34 envelope

12.0.34.1 Possible use:

- **envelope** (unknown) —> geometry

12.0.34.2 Result:

A 3D geometry that represents the box that surrounds the geometries or the surface described by the arguments. More general than geometry(arguments).envelope, as it allows to pass int, double, point, image files, shape files, asc files, or any list combining these arguments, in which case the envelope will be correctly expanded. If an envelope cannot be determined from the arguments, a default one of dimensions (0,100, 0, 100, 0, 100) is returned

---

12.0.35 eval_gaml

12.0.35.1 Possible use:

- **eval_gaml** (string) —> unknown

12.0.35.2 Result:

evaluates the given GAML string.

12.0.35.3 Examples:

```
unknown var0 <- eval_gaml("2+3"); // var0 equals 5
```

12.0.36   `eval_when`

12.0.36.1   Possible use:

- **eval_when** (BDIPlan) —> bool

12.0.36.2   Result:

evaluate the facet when of a given plan

12.0.36.3   Examples:

```
eval_when(plan1)
```

12.0.37   `evaluate_sub_model`

12.0.37.1   Possible use:

- msi.gama.kernel.experiment.IExperimentAgent **evaluate_sub_model** string —> unknown
- **evaluate_sub_model** (msi.gama.kernel.experiment.IExperimentAgent , string) —> unknown

12.0.37.2   Result:

Load a submodel

12.0.37.3   Comment:

loaded submodel

12.0.38   `even`

12.0.38.1   Possible use:

- **even** (int) —> bool

12.0.38.2   Result:

Returns true if the operand is even and false if it is odd.

12.0.38.3   Special cases:

- if the operand is equal to 0, it returns true.

- if the operand is a float, it is truncated before

12.0.38.4 Examples:

```
bool var0 <- even (3); // var0 equals false
bool var1 <- even(-12); // var1 equals true
```

12.0.39 `every`

12.0.39.1 Possible use:

- **every** (int) —> bool
- **every** (any expression) —> bool
- msi.gama.util.GamaDateInterval **every** any expression —> msi.gama.util.IList<msi.gama.util.GamaDate>
- **every** (msi.gama.util.GamaDateInterval , any expression) —> msi.gama.util.IList<msi.gama.util.GamaDate
- list **every** int —> list
- **every** (list , int) —> list

12.0.39.2 Result:

true every operand * cycle, false otherwise applies a step to an interval of dates defined by 'date1 to date2'
Retrieves elements from the first argument every `step` (second argument) elements. Raises an error if the
step is negative or equal to zero expects a frequency (expressed in seconds of simulated time) as argument.
Will return true every time the current_date matches with this frequency

12.0.39.3 Comment:

the value of the every operator depends on the cycle. It can be used to do something every x cycle.Used to
do something at regular intervals of time. Can be used in conjunction with 'since', 'after', 'before', 'until' or
'between', so that this computation only takes place in the temporal segment defined by these operators. In
all cases, the starting_date of the model is used as a reference starting point

12.0.39.4 Examples:

```
if every(2#cycle) {write "the cycle number is even";}        else {write "the cycle number is odd";} (d
```

12.0.39.5 See also:

to, since, after,

12.0.40 `every_cycle`

Same signification as every

12.0.41 `evidence_theory_DM`

12.0.41.1 Possible use:

- msi.gama.util.IList<java.util.List> **evidence_theory_DM** msi.gama.util.IList<java.util.Map<java.lang.S
  —> int
- **evidence_theory_DM** (msi.gama.util.IList<java.util.List> , msi.gama.util.IList<java.util.Map<java.lang
  —> int
- **evidence_theory_DM** (msi.gama.util.IList<java.util.List>, msi.gama.util.IList<java.util.Map<java.lang
  bool) —> int

12.0.41.2 Result:

The index of the best candidate according to a method based on the Evidence theory. This theory, which
was proposed by Shafer ([http://www.glennshafer.com/books/amte.html Shafer G (1976) A mathematical
theory of evidence, Princeton University Press]), is based on the work of Dempster ([http://projecteuclid.
org/DPubS?service=UI&version=1.0&verb=Display&handle=euclid.aoms/1177698950 Dempster A (1967)
Upper and lower probabilities induced by multivalued mapping. Annals of Mathematical Statistics, vol.
38, pp. 325–339]) on lower and upper probability distributions. The first operand is the list of candidates
(a candidate is a list of criterion values); the second operand the list of criterion: A criterion is a map
that contains seven elements: a name, a first threshold s1, a second threshold s2, a value for the assertion
"this candidate is the best" at threshold s1 (v1p), a value for the assertion "this candidate is the best" at
threshold s2 (v2p), a value for the assertion "this candidate is not the best" at threshold s1 (v1c), a value
for the assertion "this candidate is not the best" at threshold s2 (v2c). v1p, v2p, v1c and v2c have to been
defined in order that: v1p + v1c <= 1.0; v2p + v2c <= 1.0.; the last operand allows to use a simple version
of this multi-criteria decision making method (simple if true)

12.0.41.3 Special cases:

- returns -1 is the list of candidates is nil or empty

- if the operator is used with only 2 operands (the candidates and the criteria), the last parameter (use
  simple method) is set to true

12.0.41.4 Examples:

```
int var0 <- evidence_theory_DM([[1.0, 7.0],[4.0,2.0],[3.0, 3.0]], [["name"::"utility", "s1" :: 0.0,"s2"
```

12.0.41.5 See also:

weighted_means_DM, electre_DM,

12.0.42 `exp`

12.0.42.1 Possible use:

- **exp** (float) —> float
- **exp** (int) —> float

12.0.42.2 Result:

Returns Euler's number e raised to the power of the operand.

12.0.42.3 Special cases:

- the operand is casted to a float before being evaluated.

- the operand is casted to a float before being evaluated.

12.0.42.4 Examples:

```
float var0 <- exp (0); // var0 equals 1.0
```

12.0.42.5 See also:

ln,

12.0.43 fact

12.0.43.1 Possible use:

- **fact** (int) —> float

12.0.43.2 Result:

Returns the factorial of the operand.

12.0.43.3 Special cases:

- if the operand is less than 0, fact returns 0.

12.0.43.4 Examples:

```
float var0 <- fact(4); // var0 equals 24
```

12.0.44 farthest_point_to

12.0.44.1 Possible use:

- geometry **farthest_point_to** point —> point
- **farthest_point_to** (geometry , point) —> point

12.0.44.2   Result:

the farthest point of the left-operand to the left-point.

12.0.44.3   Examples:

```
point var0 <- geom farthest_point_to(pt); // var0 equals the farthest point of geom to pt
```

12.0.44.4   See also:

any_location_in, any_point_in, closest_points_with, points_at,

----

12.0.45   farthest_to

12.0.45.1   Possible use:

- container<agent> **farthest_to** geometry —> geometry
- **farthest_to** (container<agent> , geometry) —> geometry

12.0.45.2   Result:

An agent or a geometry among the left-operand list of agents, species or meta-population (addition of species),
the farthest to the operand (casted as a geometry).

12.0.45.3   Comment:

the distance is computed in the topology of the calling agent (the agent in which this operator is used), with
the distance algorithm specific to the topology.

12.0.45.4   Examples:

```
geometry var0 <- [ag1, ag2, ag3] closest_to(self); // var0 equals return the farthest agent among ag1,
```

12.0.45.5   See also:

neighbors_at, neighbors_of, inside, overlapping, agents_overlapping, agents_inside, agent_closest_to, clos-
est_to, agent_farthest_to,

12.0.46 `file`

12.0.46.1 Possible use:

- `file` (string) —> `file`
- string `file` container —> `file`
- `file` (string , container) —> `file`

12.0.46.2 Result:

opens a file in read only mode, creates a GAML file object, and tries to determine and store the file content in the contents attribute. Creates a file in read/write mode, setting its contents to the container passed in parameter

12.0.46.3 Comment:

The file should have a supported extension, see file type definition for supported file extensions.The type of container to pass will depend on the type of file (see the management of files in the documentation). Can be used to copy files since files are considered as containers. For example: save file('image_copy.png', file('image.png')); will copy image.png to image_copy.png

12.0.46.4 Special cases:

- If the specified string does not refer to an existing file, an exception is risen when the variable is used.

12.0.46.5 Examples:

let fileT type: file value: file("../includes/Stupid_Cell.Data");   // fileT represents the fil

12.0.46.6 See also:

folder, new_folder,

12.0.47 `file`

12.0.47.1 Possible use:

- `file` (any) —> `file`

12.0.47.2 Result:

Casts the operand into the type file

12.0.48 `file_exists`

12.0.48.1 Possible use:

- `file_exists` (string) —> `bool`

12.0.48.2 Result:

Test whether the parameter is the path to an existing file.

12.0.49 `first`

12.0.49.1 Possible use:

- `first` (container<KeyType,ValueType>) —> `ValueType`
- `first` (string) —> `string`
- int `first` container —> `list`
- `first` (int , container) —> `list`

12.0.49.2 Result:

the first value of the operand

12.0.49.3 Comment:

the first operator behavior depends on the nature of the operand

12.0.49.4 Special cases:

- if it is a map, first returns the first value of the first pair (in insertion order)

- if it is a file, first returns the first element of the content of the file (that is also a container)

- if it is a population, first returns the first agent of the population

- if it is a graph, first returns the first edge (in creation order)

- if it is a matrix, first returns the element at {0,0} in the matrix

- for a matrix of int or float, it will return 0 if the matrix is empty

- for a matrix of object or geometry, it will return nil if the matrix is empty

- if it is a list, first returns the first element of the list, or nil if the list is empty

```
int var0 <- first ([1, 2, 3]); // var0 equals 1
```
- if it is a string, first returns a string composed of its first character

```
string var1 <- first ('abce'); // var1 equals 'a'
```

12.0.49.5 See also:

last,

12.0.50 `first_of`

Same signification as first

12.0.51 `first_with`

12.0.51.1 Possible use:

- container **first_with** any expression —> unknown
- **first_with** (container , any expression) —> unknown

12.0.51.2 Result:

the first element of the left-hand operand that makes the right-hand operand evaluate to true.

12.0.51.3 Comment:

in the right-hand operand, the keyword each can be used to represent, in turn, each of the right-hand operand elements.

12.0.51.4 Special cases:

- if the left-hand operand is nil, first_with throws an error. If there is no element that satisfies the condition, it returns nil

- if the left-operand is a map, the keyword each will contain each value

```
unknown var4 <- [1::2, 3::4, 5::6] first_with (each >= 4); // var4 equals 4
unknown var5 <- [1::2, 3::4, 5::6].pairs first_with (each.value >= 4); // var5 equals (3::4)
```

12.0.51.5 Examples:

```
unknown var0 <- [1,2,3,4,5,6,7,8] first_with (each > 3); // var0 equals 4
unknown var2 <- g2 first_with (length(g2 out_edges_of each) = 0); // var2 equals node9
unknown var3 <- (list(node) first_with (round(node(each).location.x) > 32); // var3 equals node2
```

group_by, last_with, where,

12.0.52   `flip`

12.0.52.1   Possible use:

- **flip** (float) —> bool

12.0.52.2   Result:

true or false given the probability represented by the operand

12.0.52.3   Special cases:

- flip 0 always returns false, flip 1 true

12.0.52.4   Examples:

```
bool var0 <- flip (0.66666); // var0 equals 2/3 chances to return true.
```

12.0.52.5   See also:

rnd,

12.0.53   `float`

12.0.53.1   Possible use:

- **float** (any) —> float

12.0.53.2   Result:

Casts the operand into the type float

12.0.54   `floor`

12.0.54.1   Possible use:

- **floor** (float) —> float

12.0.54.2 Result:

Maps the operand to the largest previous following integer, i.e. the largest integer not greater than x.

12.0.54.3 Examples:

```
float var0 <- floor(3); // var0 equals 3.0
float var1 <- floor(3.5); // var1 equals 3.0
float var2 <- floor(-4.7); // var2 equals -5.0
```

12.0.54.4 See also:

ceil, round,

12.0.55 folder

12.0.55.1 Possible use:

- **folder** (string) —> file

12.0.55.2 Result:

opens an existing repository

12.0.55.3 Special cases:

- If the specified string does not refer to an existing repository, an exception is risen.

12.0.55.4 Examples:

```
file dirT <- folder("../includes/");          // dirT represents the repository "../includes/"
```

12.0.55.5 See also:

file, new_folder,

12.0.56 font

12.0.56.1 Possible use:

- **font** (string, int, int) —> font

12.0.56.2   Result:

Creates a new font, by specifying its name (either a font face name like 'Lucida Grande Bold' or 'Helvetica', or a logical name like 'Dialog', 'SansSerif', 'Serif', etc.), a size in points and a style, either #bold, #italic or #plain or a combination (addition) of them.

12.0.56.3   Examples:

```
font var0 <- font ('Helvetica Neue',12, #bold + #italic); // var0 equals a bold and italic face of the
```

12.0.57   `frequency_of`

12.0.57.1   Possible use:

- container **frequency_of** any expression —> map
- **frequency_of** (container , any expression) —> map

12.0.57.2   Result:

Returns a map with keys equal to the application of the right-hand argument (like collect) and values equal to the frequency of this key (i.e. how many times it has been obtained)

12.0.57.3   Examples:

```
map var0 <- [ag1, ag2, ag3, ag4] frequency_of each.size; // var0 equals the different sizes as keys and
```

12.0.57.4   See also:

as_map,

12.0.58   `from`

Same signification as since

12.0.59   `fuzzy_choquet_DM`

12.0.59.1   Possible use:

- **fuzzy_choquet_DM** (msi.gama.util.IList<java.util.List>, list<string>, map) —> int

12.0.59.2 Result:

The index of the candidate that maximizes the Fuzzy Choquet Integral value. The first operand is the list of candidates (a candidate is a list of criterion values); the second operand the list of criterion (list of string); the third operand the weights of each sub-set of criteria (map with list for key and float for value)

12.0.59.3 Special cases:

- returns -1 is the list of candidates is nil or empty

12.0.59.4 Examples:

```
int var0 <- fuzzy_choquet_DM([[1.0, 7.0],[4.0,2.0],[3.0, 3.0]], ["utility", "price", "size"],[["utility"
```

12.0.59.5 See also:

promethee_DM, electre_DM, evidence_theory_DM,

12.0.60 `fuzzy_kappa`

12.0.60.1 Possible use:

- **`fuzzy_kappa`** (list<agent>, list, list, list<float>, list, matrix<float>, float) —> float
- **`fuzzy_kappa`** (list<agent>, list, list, list<float>, list, matrix<float>, float, list) —> float

12.0.60.2 Result:

fuzzy kappa indicator for 2 map comparisons: fuzzy_kappa(agents_list,list_vals1,list_vals2, output_similarity_per_agents,categories,fuzzy_categories_matrix, fuzzy_distance, weights). Reference: Visser, H., and T. de Nijs, 2006. The map comparison kit, Environmental Modelling & Software, 21 fuzzy kappa indicator for 2 map comparisons: fuzzy_kappa(agents_list,list_vals1,list_vals2, output_similarity_per_agents,categories,fuzzy_categories_matrix, fuzzy_distance). Reference: Visser, H., and T. de Nijs, 2006. The map comparison kit, Environmental Modelling & Software, 21

12.0.60.3 Examples:

```
fuzzy_kappa([ag1, ag2, ag3, ag4, ag5],[cat1,cat1,cat2,cat3,cat2],[cat2,cat1,cat2,cat1,cat2], similarity_
```

12.0.61 `fuzzy_kappa_sim`

12.0.61.1 Possible use:

- **`fuzzy_kappa_sim`** (list<agent>, list, list, list, list<float>, list, matrix<float>, float) —> float

- `fuzzy_kappa_sim` (list<agent>, list, list, list, list<float>, list, matrix<float>, float, list)
  —> float

12.0.61.2 Result:

fuzzy kappa simulation indicator for 2 map comparisons: fuzzy_kappa_sim(agents_list,list_vals1,list_vals2, output_similarity_per_agents,fuzzy_transitions_matrix, fuzzy_distance, weights). Reference: Jasper van Vliet, Alex Hagen-Zanker, Jelle Hurkens, Hedwig van Delden, A fuzzy set approach to assess the predictive accuracy of land use simulations, Ecological Modelling, 24 July 2013, Pages 32-42, ISSN 0304-3800, fuzzy kappa simulation indicator for 2 map comparisons: fuzzy_kappa_sim(agents_list,list_vals1,list_vals2, output_similarity_per_agents,fuzzy_transitions_matrix, fuzzy_distance). Reference: Jasper van Vliet, Alex Hagen-Zanker, Jelle Hurkens, Hedwig van Delden, A fuzzy set approach to assess the predictive accuracy of land use simulations, Ecological Modelling, 24 July 2013, Pages 32-42, ISSN 0304-3800,

12.0.61.3 Examples:

```
fuzzy_kappa_sim([ag1, ag2, ag3, ag4, ag5], [cat1,cat1,cat2,cat3,cat2],[cat2,cat1,cat2,cat1,cat2], simila
```

12.0.62 `gaml_file`

12.0.62.1 Possible use:

- `gaml_file` (string) —> file

12.0.62.2 Result:

Constructs a file of type gaml. Allowed extensions are limited to gaml, experiment

---

12.0.63 `gaml_type`

12.0.63.1 Possible use:

- `gaml_type` (any) —> gaml_type

12.0.63.2 Result:

Casts the operand into the type gaml_type

12.0.64 `gamma`

12.0.64.1 Possible use:

- `gamma` (float) —> float

12.0.64.2 Result:

Returns the value of the Gamma function at x.

12.0.65 `gamma_distribution`

12.0.65.1 Possible use:

- **gamma_distribution** (float, float, float) —> float

12.0.65.2 Result:

Returns the integral from zero to x of the gamma probability density function.

12.0.65.3 Comment:

incomplete_gamma(a,x) is equal to pgamma(a,1,x).

12.0.66 `gamma_distribution_complemented`

12.0.66.1 Possible use:

- **gamma_distribution_complemented** (float, float, float) —> float

12.0.66.2 Result:

Returns the integral from x to infinity of the gamma probability density function.

12.0.67 `gamma_index`

12.0.67.1 Possible use:

- **gamma_index** (graph) —> float

12.0.67.2 Result:

returns the gamma index of the graph (A measure of connectivity that considers the relationship between the number of observed links and the number of possible links: gamma = e/(3 * (v - 2)) - for planar graph.

12.0.67.3 Examples:

```
graph graphEpidemio <- graph([]);
float var1 <- gamma_index(graphEpidemio); // var1 equals the gamma index of the graph
```

12.0.67.4 See also:

alpha_index, beta_index, nb_cycles, connectivity_index,

12.0.68 `gamma_rnd`

12.0.68.1 Possible use:

- float **gamma_rnd** float —> float
- **gamma_rnd** (float , float) —> float

12.0.68.2 Result:

returns a random value from a gamma distribution with specified values of the shape and scale parameters

12.0.68.3 Examples:

```
gamma_rnd(10.0,5.0)
```

12.0.69 `gauss`

12.0.69.1 Possible use:

- **gauss** (point) —> float
- float **gauss** float —> float
- **gauss** (float , float) —> float

12.0.69.2 Result:

A value from a normally distributed random variable with expected value (mean as first operand) and variance (standardDeviation as second operand). The probability density function of such a variable is a Gaussian. The operator can be used with an operand of type point {meand,standardDeviation}.

12.0.69.3 Special cases:

- when standardDeviation value is 0.0, it always returns the mean value

- when the operand is a point, it is read as {mean, standardDeviation}

12.0.69.4 Examples:

```
float var0 <- gauss(0,0.3); // var0 equals 0.22354
float var1 <- gauss({0,0.3}); // var1 equals 0.22354
```

12.0.69.5   See also:

skew__gauss, truncated__gauss, poisson,

12.0.70   `generate_barabasi_albert`

12.0.70.1   Possible use:

- **generate_barabasi_albert** (container<agent>, species, int, bool) —> graph
- **generate_barabasi_albert** (species, species, int, int, bool) —> graph

12.0.70.2   Result:

returns a random scale-free network (following Barabasi-Albert (BA) model). returns a random scale-free network (following Barabasi-Albert (BA) model).

12.0.70.3   Comment:

The Barabasi-Albert (BA) model is an algorithm for generating random scale-free networks using a preferential attachment mechanism. A scale-free network is a network whose degree distribution follows a power law, at least asymptotically.Such networks are widely observed in natural and human-made systems, including the Internet, the world wide web, citation networks, and some social networks. [From Wikipedia article]The map operand should includes following elements:The Barabasi-Albert (BA) model is an algorithm for generating random scale-free networks using a preferential attachment mechanism. A scale-free network is a network whose degree distribution follows a power law, at least asymptotically.Such networks are widely observed in natural and human-made systems, including the Internet, the world wide web, citation networks, and some social networks. [From Wikipedia article]The map operand should includes following elements:

12.0.70.4   Special cases:

- "vertices_specy": the species of vertices

- "edges_species": the species of edges

- "size": the graph will contain (size + 1) nodes

- "m": the number of edges added per novel node

- "synchronized": is the graph and the species of vertices and edges synchronized?

- "agents": list of existing node agents

- "edges_species": the species of edges

- "size": the graph will contain (size + 1) nodes

- "m": the number of edges added per novel node

- "synchronized": is the graph and the species of vertices and edges synchronized?

12.0.70.5   Examples:

graph<yourNodeSpecy,yourEdgeSpecy> graphEpidemio <- generate_barabasi_albert(yourNodeSpecy,

12.0.70.6   See also:

12.0.72.1 Possible use:

- **generate_watts_strogatz** (container<agent>, species, float, int, bool) —> graph
- **generate_watts_strogatz** (species, species, int, float, int, bool) —> graph

12.0.72.2 Result:

returns a random small-world network (following Watts-Strogatz model). returns a random small-world network (following Watts-Strogatz model).

12.0.72.3 Comment:

The Watts-Strogatz model is a random graph generation model that produces graphs with small-world properties, including short average path lengths and high clustering.A small-world network is a type of graph in which most nodes are not neighbors of one another, but most nodes can be reached from every other by a small number of hops or steps. [From Wikipedia article]The map operand should includes following elements:The Watts-Strogatz model is a random graph generation model that produces graphs with small-world properties, including short average path lengths and high clustering.A small-world network is a type of graph in which most nodes are not neighbors of one another, but most nodes can be reached from every other by a small number of hops or steps. [From Wikipedia article]The map operand should includes following elements:

12.0.72.4 Special cases:

- "vertices_specy": the species of vertices

- "edges_species": the species of edges

- "size": the graph will contain (size + 1) nodes. Size must be greater than k.

- "p": probability to "rewire" an edge. So it must be between 0 and 1. The parameter is often called beta in the literature.

- "k": the base degree of each node. k must be greater than 2 and even.

- "synchronized": is the graph and the species of vertices and edges synchronized?

- "agents": list of existing node agents

- "edges_species": the species of edges

12.0.73 `geojson_file`

12.0.73.1 Possible use:

- **geojson_file** (string) —> file

12.0.73.2 Result:

Constructs a file of type geojson. Allowed extensions are limited to json, geojson, geo.json

---

12.0.74 `geometric_mean`

12.0.74.1 Possible use:

- **`geometric_mean`** (container) —> float

12.0.74.2 Result:

the geometric mean of the elements of the operand. See Geometric_mean for more details.

12.0.74.3 Comment:

The operator casts all the numerical element of the list into float. The elements that are not numerical are discarded.

12.0.74.4 Examples:

```
float var0 <- geometric_mean ([4.5, 3.5, 5.5, 7.0]); // var0 equals 4.962326343467649
```

12.0.74.5 See also:

mean, median, harmonic_mean,

12.0.75 `geometry`

12.0.75.1 Possible use:

- **`geometry`** (any) —> geometry

12.0.75.2 Result:

Casts the operand into the type geometry

12.0.76 `geometry_collection`

12.0.76.1 Possible use:

- **`geometry_collection`** (container<geometry>) —> geometry

12.0.76.2 Result:

A geometry collection (multi-geometry) composed of the given list of geometries.

12.0.76.3 Special cases:

- if the operand is nil, returns the point geometry {0,0}

- if the operand is composed of a single geometry, returns a copy of the geometry.

12.0.76.4 Examples:

```
geometry var0 <- geometry_collection([{0,0}, {0,10}, {10,10}, {10,0}]); // var0 equals a geometry compo
```

12.0.77 `get`

12.0.77.1 Possible use:

- geometry **get** string —> unknown
- **get** (geometry , string) —> unknown
- agent **get** string —> unknown
- **get** (agent , string) —> unknown

12.0.77.2 Result:

Reads an attribute of the specified geometry (left operand). The attribute name is specified by the right operand. Reads an attribute of the specified agent (left operand). The attribute name is specified by the right operand.

12.0.77.3 Special cases:

- Reading the attribute of a geometry

```
string geom_area <- a_geometry get('area');      // reads then 'area' attribute of 'a_geometry' variable
```

- Reading the attribute of another agent

```
string agent_name <- an_agent get('name');       // reads then 'name' attribute of an_agent then assigns
```

12.0.78 `get_about`

12.0.78.1 Possible use:

- **get_about** (emotion) —> predicate

12.0.78.2 Result:

get the about value of the given emotion

12.0.78.3 Examples:

```
get_about(emotion)
```

12.0.79 get_agent

12.0.79.1 Possible use:

- **get_agent** (msi.gaml.architecture.simplebdi.SocialLink) —> agent

12.0.79.2 Result:

get the agent value of the given social link

12.0.79.3 Examples:

```
get_agent(social_link1)
```

12.0.80 get_agent_cause

12.0.80.1 Possible use:

- **get_agent_cause** (emotion) —> agent
- **get_agent_cause** (predicate) —> agent

12.0.80.2 Result:

get the agent cause value of the given emotion

12.0.80.3 Examples:

```
get_agent_cause(emotion)
```

12.0.81 get_belief_op

12.0.81.1 Possible use:

- agent **get_belief_op** predicate —> mental_state
- **get_belief_op** (agent , predicate) —> mental_state

12.0.81.2 Result:

get the belief in the belief base with the given predicate.

12.0.81.3 Examples:

```
get_belief_op(self,has_water)
```

12.0.82 get_belief_with_name_op

12.0.82.1 Possible use:

- agent **get_belief_with_name_op** string —> mental_state
- **get_belief_with_name_op** (agent , string) —> mental_state

12.0.82.2 Result:

get the belief in the belief base with the given name.

12.0.82.3 Examples:

```
get_belief_with_name_op(self,"has_water")
```

12.0.83 get_beliefs_op

12.0.83.1 Possible use:

- agent **get_beliefs_op** predicate —> msi.gama.util.IList<msi.gaml.architecture.simplebdi.MentalState>
- **get_beliefs_op** (agent , predicate) —> msi.gama.util.IList<msi.gaml.architecture.simplebdi.MentalState

12.0.83.2 Result:

get the beliefs in the belief base with the given predicate.

12.0.83.3 Examples:

```
get_beliefs_op(self,has_water)
```

12.0.84 `get_beliefs_with_name_op`

12.0.84.1 Possible use:

- agent **get_beliefs_with_name_op** string —> msi.gama.util.IList<msi.gaml.architecture.simplebdi.MentalS
- **get_beliefs_with_name_op** (agent , string) —> msi.gama.util.IList<msi.gaml.architecture.simplebdi.Ment

12.0.84.2 Result:

get the list of beliefs in the belief base which predicate has the given name.

12.0.84.3 Examples:

```
get_beliefs_with_name_op(self,"has_water")
```

12.0.85 `get_current_intention_op`

12.0.85.1 Possible use:

- **get_current_intention_op** (agent) —> mental_state

12.0.85.2 Result:

get the current intention.

12.0.85.3 Examples:

```
get_current_intention_op(self,has_water)
```

12.0.86 `get_decay`

12.0.86.1 Possible use:

- **get_decay** (emotion) —> float

12.0.86.2 Result:

get the decay value of the given emotion

12.0.86.3 Examples:

```
get_decay(emotion)
```

12.0.87 `get_desire_op`

12.0.87.1 Possible use:

- agent **get_desire_op** predicate —> mental_state
- **get_desire_op** (agent , predicate) —> mental_state

12.0.87.2 Result:

get the desire in the desire base with the given predicate.

12.0.87.3 Examples:

```
get_belief_op(self,has_water)
```

12.0.88 `get_desire_with_name_op`

12.0.88.1 Possible use:

- agent **get_desire_with_name_op** string —> mental_state
- **get_desire_with_name_op** (agent , string) —> mental_state

12.0.88.2 Result:

get the desire in the desire base with the given name.

12.0.88.3 Examples:

```
mental_state var0 <- get_desire_with_name_op(self,"has_water"); // var0 equals nil
```

12.0.89 `get_desires_op`

12.0.89.1 Possible use:

- agent **get_desires_op** predicate —> msi.gama.util.IList<msi.gaml.architecture.simplebdi.MentalState>
- **get_desires_op** (agent , predicate) —> msi.gama.util.IList<msi.gaml.architecture.simplebdi.MentalState>

12.0.89.2 Result:

get the desires in the desire base with the given predicate.

12.0.89.3 Examples:

```
get_desires_op(self,has_water)
```

12.0.90 `get_desires_with_name_op`

12.0.90.1 Possible use:

- agent **get_desires_with_name_op** string —> msi.gama.util.IList<msi.gaml.architecture.simplebdi.MentalS
- **get_desires_with_name_op** (agent , string) —> msi.gama.util.IList<msi.gaml.architecture.simplebdi.Ment

12.0.90.2 Result:

get the list of desires in the desire base which predicate has the given name.

12.0.90.3 Examples:

```
get_desires_with_name_op(self,"has_water")
```

12.0.91 `get_dominance`

12.0.91.1 Possible use:

- **get_dominance** (msi.gaml.architecture.simplebdi.SocialLink) —> float

12.0.91.2 Result:

get the dominance value of the given social link

12.0.91.3 Examples:

```
get_dominance(social_link1)
```

12.0.92 `get_familiarity`

12.0.92.1 Possible use:

- **get_familiarity** (msi.gaml.architecture.simplebdi.SocialLink) —> float

12.0.92.2 Result:

get the familiarity value of the given social link

12.0.92.3 Examples:

```
get_familiarity(social_link1)
```

12.0.93 `get_ideal_op`

12.0.93.1 Possible use:

- agent **get_ideal_op** predicate —> mental_state
- **get_ideal_op** (agent , predicate) —> mental_state

12.0.93.2 Result:

get the ideal in the ideal base with the given name.

12.0.93.3 Examples:

```
get_ideal_op(self,has_water)
```

12.0.94 `get_ideal_with_name_op`

12.0.94.1 Possible use:

- agent **get_ideal_with_name_op** string —> mental_state
- **get_ideal_with_name_op** (agent , string) —> mental_state

12.0.94.2 Result:

get the ideal in the ideal base with the given name.

12.0.94.3 Examples:

```
get_ideal_with_name_op(self,"has_water")
```

12.0.95 `get_ideals_op`

12.0.95.1 Possible use:

- agent **get_ideals_op** predicate —> msi.gama.util.IList<msi.gaml.architecture.simplebdi.MentalState>
- **get_ideals_op** (agent , predicate) —> msi.gama.util.IList<msi.gaml.architecture.simplebdi.MentalState>

12.0.95.2 Result:

get the ideal in the ideal base with the given name.

12.0.95.3 Examples:

```
get_ideals_op(self,has_water)
```

12.0.96 get_ideals_with_name_op

12.0.96.1 Possible use:

- agent **get_ideals_with_name_op** string —> msi.gama.util.IList<msi.gaml.architecture.simplebdi.MentalSt
- **get_ideals_with_name_op** (agent , string) —> msi.gama.util.IList<msi.gaml.architecture.simplebdi.Menta

12.0.96.2 Result:

get the list of ideals in the ideal base which predicate has the given name.

12.0.96.3 Examples:

```
get_ideals_with_name_op(self,"has_water")
```

12.0.97 get_intensity

12.0.97.1 Possible use:

- **get_intensity** (emotion) —> float

12.0.97.2 Result:

get the intensity value of the given emotion

12.0.97.3 Examples:

```
emotion set_intensity 12
```

12.0.98 get_intention_op

12.0.98.1 Possible use:

- agent **get_intention_op** predicate —> mental_state
- **get_intention_op** (agent , predicate) —> mental_state

12.0.98.2 Result:

get the intention in the intention base with the given predicate.

12.0.98.3 Examples:

```
get_intention_op(self,has_water)
```

12.0.99 get_intention_with_name_op

12.0.99.1 Possible use:

- agent **get_intention_with_name_op** string —> mental_state
- **get_intention_with_name_op** (agent , string) —> mental_state

12.0.99.2 Result:

get the intention in the intention base with the given name.

12.0.99.3 Examples:

```
get_intention_with_name_op(self,"has_water")
```

12.0.100 get_intentions_op

12.0.100.1 Possible use:

- agent **get_intentions_op** predicate —> msi.gama.util.IList<msi.gaml.architecture.simplebdi.MentalState
- **get_intentions_op** (agent , predicate) —> msi.gama.util.IList<msi.gaml.architecture.simplebdi.MentalSt

12.0.100.2 Result:

get the intentions in the intention base with the given predicate.

12.0.100.3 Examples:

```
get_intentions_op(self,has_water)
```

12.0.101 `get_intentions_with_name_op`

12.0.101.1 Possible use:

- agent **get_intentions_with_name_op** string —> msi.gama.util.IList<msi.gaml.architecture.simplebdi.Ment
- **get_intentions_with_name_op** (agent , string) —> msi.gama.util.IList<msi.gaml.architecture.simplebdi.M

12.0.101.2 Result:

get the list of intentions in the intention base which predicate has the given name.

12.0.101.3 Examples:

```
get_intentions_with_name_op(self,"has_water")
```

12.0.102 `get_lifetime`

12.0.102.1 Possible use:

- **get_lifetime** (predicate) —> int
- **get_lifetime** (mental_state) —> int

12.0.102.2 Result:

get the lifetime value of the given mental state

12.0.102.3 Examples:

```
get_lifetime(mental_state1)
```

12.0.103 `get_liking`

12.0.103.1 Possible use:

- **get_liking** (msi.gaml.architecture.simplebdi.SocialLink) —> float

12.0.103.2 Result:

get the liking value of the given social link

12.0.103.3 Examples:

```
get_liking(social_link1)
```

12.0.104 `get_modality`

12.0.104.1 Possible use:

- **`get_modality`** (mental_state) —> `string`

12.0.104.2 Result:

get the modality value of the given mental state

12.0.104.3 Examples:

```
get_modality(mental_state1)
```

12.0.105 `get_obligation_op`

12.0.105.1 Possible use:

- agent **`get_obligation_op`** predicate —> `mental_state`
- **`get_obligation_op`** (agent , predicate) —> `mental_state`

12.0.105.2 Result:

get the obligation in the obligation base with the given predicate.

12.0.105.3 Examples:

```
get_obligation_op(self,has_water)
```

12.0.106 `get_obligation_with_name_op`

12.0.106.1 Possible use:

- agent **`get_obligation_with_name_op`** string —> `mental_state`
- **`get_obligation_with_name_op`** (agent , string) —> `mental_state`

12.0.106.2 Result:

get the obligation in the obligation base with the given name.

12.0.106.3 Examples:

```
get_obligation_with_name_op(self,"has_water")
```

12.0.107 `get_obligations_op`

12.0.107.1 Possible use:

- agent **get_obligations_op** predicate —> msi.gama.util.IList<msi.gaml.architecture.simplebdi.MentalStat
- **get_obligations_op** (agent , predicate) —> msi.gama.util.IList<msi.gaml.architecture.simplebdi.MentalS

12.0.107.2 Result:

get the obligations in the obligation base with the given predicate.

12.0.107.3 Examples:

get_obligations_op(self,has_water)

12.0.108 `get_obligations_with_name_op`

12.0.108.1 Possible use:

- agent **get_obligations_with_name_op** string —> msi.gama.util.IList<msi.gaml.architecture.simplebdi.Men
- **get_obligations_with_name_op** (agent , string) —> msi.gama.util.IList<msi.gaml.architecture.simplebdi.

12.0.108.2 Result:

get the list of obligations in the obligation base which predicate has the given name.

12.0.108.3 Examples:

get_obligations_with_name_op(self,"has_water")

12.0.109 `get_plan_name`

12.0.109.1 Possible use:

- **get_plan_name** (BDIPlan) —> string

12.0.109.2 Result:

get the name of a given plan

12.0.109.3 Examples:

get_plan_name(agent.current_plan)

12.0.110 get_predicate

12.0.110.1 Possible use:

- **get_predicate** (mental_state) —> predicate

12.0.110.2 Result:

get the predicate value of the given mental state

12.0.110.3 Examples:

get_predicate(mental_state1)

12.0.111 get_solidarity

12.0.111.1 Possible use:

- **get_solidarity** (msi.gaml.architecture.simplebdi.SocialLink) —> float

12.0.111.2 Result:

get the solidarity value of the given social link

12.0.111.3 Examples:

get_solidarity(social_link1)

12.0.112 get_strength

12.0.112.1 Possible use:

- **get_strength** (mental_state) —> float

12.0.112.2 Result:

get the strength value of the given mental state

12.0.112.3 Examples:

get_strength(mental_state1)

12.0.113 `get_super_intention`

12.0.113.1 Possible use:

- **get_super_intention** (predicate) —> mental_state

12.0.114 `get_trust`

12.0.114.1 Possible use:

- **get_trust** (msi.gaml.architecture.simplebdi.SocialLink) —> float

12.0.114.2 Result:

get the familiarity value of the given social link

12.0.114.3 Examples:

get_familiarity(social_link1)

12.0.115 `get_truth`

12.0.115.1 Possible use:

- **get_truth** (predicate) —> bool

12.0.116 `get_uncertainties_op`

12.0.116.1 Possible use:

- agent **get_uncertainties_op** predicate —> msi.gama.util.IList<msi.gaml.architecture.simplebdi.MentalSt
- **get_uncertainties_op** (agent , predicate) —> msi.gama.util.IList<msi.gaml.architecture.simplebdi.Menta

12.0.116.2 Result:

get the uncertainties in the uncertainty base with the given predicate.

12.0.116.3 Examples:

get_uncertinties_op(self,has_water)

12.0.117 `get_uncertainties_with_name_op`

12.0.117.1 Possible use:

- agent **get_uncertainties_with_name_op** string —> msi.gama.util.IList<msi.gaml.architecture.simplebdi.N
- **get_uncertainties_with_name_op** (agent , string) —> msi.gama.util.IList<msi.gaml.architecture.simplebd

12.0.117.2 Result:

get the list of uncertainties in the uncertainty base which predicate has the given name.

12.0.117.3 Examples:

get_uncertainties_with_name_op(self,"has_water")

12.0.118 `get_uncertainty_op`

12.0.118.1 Possible use:

- agent **get_uncertainty_op** predicate —> mental_state
- **get_uncertainty_op** (agent , predicate) —> mental_state

12.0.118.2 Result:

get the uncertainty in the uncertainty base with the given predicate.

12.0.118.3 Examples:

get_uncertainty_op(self,has_water)

12.0.119 `get_uncertainty_with_name_op`

12.0.119.1 Possible use:

- agent **get_uncertainty_with_name_op** string —> mental_state
- **get_uncertainty_with_name_op** (agent , string) —> mental_state

12.0.119.2 Result:

get the uncertainty in the uncertainty base with the given name.

12.0.119.3 Examples:

get_uncertainty_with_name_op(self,"has_water")

12.0.120 `gif_file`

12.0.120.1 Possible use:

- `gif_file` (string) —> file

12.0.120.2 Result:

Constructs a file of type gif. Allowed extensions are limited to gif

---

12.0.121 `gini`

12.0.121.1 Possible use:

- `gini` (list<float>) —> float

12.0.121.2 Special cases:

- return the Gini Index of the given list of values (list of floats)

```
float var0 <- gini([1.0, 0.5, 2.0]); // var0 equals the gini index computed
```

12.0.122 `gml_file`

12.0.122.1 Possible use:

- `gml_file` (string) —> file

12.0.122.2 Result:

Constructs a file of type gml. Allowed extensions are limited to gml

---

12.0.123 `graph`

12.0.123.1 Possible use:

- `graph` (any) —> graph

12.0.123.2 Result:

Casts the operand into the type graph

12.0.124 `grayscale`

12.0.124.1 Possible use:

- **grayscale** (rgb) —> rgb

12.0.124.2 Result:

Converts rgb color to grayscale value

12.0.124.3 Comment:

r=red, g=green, b=blue. Between 0 and 255 and gray = 0.299 * red + 0.587 * green + 0.114 * blue (Photoshop value)

12.0.124.4 Examples:

```
rgb var0 <- grayscale (rgb(255,0,0)); // var0 equals to a dark grey
```

12.0.124.5 See also:

rgb, hsb,

12.0.125 `grid_at`

12.0.125.1 Possible use:

- species **grid_at** point —> agent
- **grid_at** (species , point) —> agent

12.0.125.2 Result:

returns the cell of the grid (right-hand operand) at the position given by the right-hand operand

12.0.125.3 Comment:

If the left-hand operand is a point of floats, it is used as a point of ints.

12.0.125.4 Special cases:

- if the left-hand operand is not a grid cell species, returns nil

12.0.125.5 Examples:

```
agent var0 <- grid_cell grid_at {1,2}; // var0 equals the agent grid_cell with grid_x=1 and grid_y = 2
```

12.0.126 `grid_cells_to_graph`

12.0.126.1 Possible use:

- **`grid_cells_to_graph`** (container) —> graph

12.0.126.2 Result:

creates a graph from a list of cells (operand). An edge is created between neighbors.

12.0.126.3 Examples:

```
my_cell_graph<-grid_cells_to_graph(cells_list)
```

12.0.127 `grid_file`

12.0.127.1 Possible use:

- **`grid_file`** (string) —> file

12.0.127.2 Result:

Constructs a file of type grid. Allowed extensions are limited to asc, tif

---

12.0.128 `group_by`

12.0.128.1 Possible use:

- container **`group_by`** any expression —> map
- **`group_by`** (container , any expression) —> map

12.0.128.2 Result:

Returns a map, where the keys take the possible values of the right-hand operand and the map values are the list of elements of the left-hand operand associated to the key value

12.0.128.3   Comment:

in the right-hand operand, the keyword each can be used to represent, in turn, each of the right-hand operand
elements.

12.0.128.4   Special cases:

- if the left-hand operand is nil, group_by throws an error

12.0.128.5   Examples:

```
map var0 <- [1,2,3,4,5,6,7,8] group_by (each > 3); // var0 equals [false::[1, 2, 3], true::[4, 5, 6, 7,
map var1 <- g2 group_by (length(g2 out_edges_of each) ); // var1 equals [ 0::[node9, node7, node10, node
map var2 <- (list(node) group_by (round(node(each).location.x)); // var2 equals [32::[node5], 21::[node
map<bool,list> var3 <- [1::2, 3::4, 5::6] group_by (each > 4); // var3 equals [false::[2, 4], true::[6]]
```

12.0.128.6   See also:

first_with, last_with, where,

12.0.129   `harmonic_mean`

12.0.129.1   Possible use:

- **harmonic_mean** (container) —> float

12.0.129.2   Result:

the harmonic mean of the elements of the operand. See Harmonic_mean for more details.

12.0.129.3   Comment:

The operator casts all the numerical element of the list into float. The elements that are not numerical are
discarded.

12.0.129.4   Examples:

```
float var0 <- harmonic_mean ([4.5, 3.5, 5.5, 7.0]); // var0 equals 4.804159445407279
```

12.0.129.5   See also:

mean, median, geometric_mean,

12.0.130 `has_belief_op`

12.0.130.1 Possible use:

- agent **has_belief_op** predicate —> bool
- **has_belief_op** (agent , predicate) —> bool

12.0.130.2 Result:

indicates if there already is a belief about the given predicate.

12.0.130.3 Examples:

has_belief_op(self,has_water)

12.0.131 `has_belief_with_name_op`

12.0.131.1 Possible use:

- agent **has_belief_with_name_op** string —> bool
- **has_belief_with_name_op** (agent , string) —> bool

12.0.131.2 Result:

indicates if there already is a belief about the given name.

12.0.131.3 Examples:

has_belief_with_name_op(self,"has_water")

12.0.132 `has_desire_op`

12.0.132.1 Possible use:

- agent **has_desire_op** predicate —> bool
- **has_desire_op** (agent , predicate) —> bool

12.0.132.2 Result:

indicates if there already is a desire about the given predicate.

12.0.132.3 Examples:

has_desire_op(self,has_water)

12.0.133 `has_desire_with_name_op`

12.0.133.1 Possible use:

- agent **has_desire_with_name_op** string —> bool
- **has_desire_with_name_op** (agent , string) —> bool

12.0.133.2 Result:

indicates if there already is a desire about the given name.

12.0.133.3 Examples:

has_desire_with_name_op(self,"has_water")

12.0.134 `has_ideal_op`

12.0.134.1 Possible use:

- agent **has_ideal_op** predicate —> bool
- **has_ideal_op** (agent , predicate) —> bool

12.0.134.2 Result:

indicates if there already is an ideal about the given predicate.

12.0.134.3 Examples:

has_ideal_op(self,has_water)

12.0.135 `has_ideal_with_name_op`

12.0.135.1 Possible use:

- agent **has_ideal_with_name_op** string —> bool
- **has_ideal_with_name_op** (agent , string) —> bool

12.0.135.2 Result:

indicates if there already is an ideal about the given name.

12.0.135.3 Examples:

has_ideal_with_name_op(self,"has_water")

12.0.136 `has_intention_op`

12.0.136.1 Possible use:

- agent **has_intention_op** predicate —> bool
- **has_intention_op** (agent , predicate) —> bool

12.0.136.2 Result:

indicates if there already is an intention about the given predicate.

12.0.136.3 Examples:

`has_intention_op(self,has_water)`

12.0.137 `has_intention_with_name_op`

12.0.137.1 Possible use:

- agent **has_intention_with_name_op** string —> bool
- **has_intention_with_name_op** (agent , string) —> bool

12.0.137.2 Result:

indicates if there already is an intention about the given name.

12.0.137.3 Examples:

`has_intention_with_name_op(self,"has_water")`

12.0.138 `has_obligation_op`

12.0.138.1 Possible use:

- agent **has_obligation_op** predicate —> bool
- **has_obligation_op** (agent , predicate) —> bool

12.0.138.2 Result:

indicates if there already is an obligation about the given predicate.

12.0.138.3 Examples:

`has_obligation_op(self,has_water)`

12.0.139   `has_obligation_with_name_op`

12.0.139.1   Possible use:

- agent **has_obligation_with_name_op** string —> bool
- **has_obligation_with_name_op** (agent , string) —> bool

12.0.139.2   Result:

indicates if there already is an obligation about the given name.

12.0.139.3   Examples:

has_obligation_with_name_op(self,"has_water")

12.0.140   `has_uncertainty_op`

12.0.140.1   Possible use:

- agent **has_uncertainty_op** predicate —> bool
- **has_uncertainty_op** (agent , predicate) —> bool

12.0.140.2   Result:

indicates if there already is an uncertainty about the given predicate.

12.0.140.3   Examples:

has_uncertainty_op(self,has_water)

12.0.141   `has_uncertainty_with_name_op`

12.0.141.1   Possible use:

- agent **has_uncertainty_with_name_op** string —> bool
- **has_uncertainty_with_name_op** (agent , string) —> bool

12.0.141.2   Result:

indicates if there already is an uncertainty about the given name.

12.0.141.3   Examples:

has_uncertainty_with_name_op(self,"has_water")

12.0.142 `hexagon`

12.0.142.1 Possible use:

- **hexagon** (float) —> geometry
- **hexagon** (point) —> geometry
- float **hexagon** float —> geometry
- **hexagon** (float , float) —> geometry

12.0.142.2 Result:

A hexagon geometry which the given with and height

12.0.142.3 Comment:

the center of the hexagon is by default the location of the current agent in which has been called this operator.the center of the hexagon is by default the location of the current agent in which has been called this operator.the center of the hexagon is by default the location of the current agent in which has been called this operator.

12.0.142.4 Special cases:

- returns nil if the operand is nil.

- returns nil if the operand is nil.

- returns nil if the operand is nil.

12.0.142.5 Examples:

```
geometry var0 <- hexagon(10); // var0 equals a geometry as a hexagon of width of 10 and height of 10.
geometry var1 <- hexagon({10,5}); // var1 equals a geometry as a hexagon of width of 10 and height of 5
geometry var2 <- hexagon(10,5); // var2 equals a geometry as a hexagon of width of 10 and height of 5.
```

12.0.142.6 See also:

around, circle, cone, line, link, norm, point, polygon, polyline, rectangle, triangle,

---

12.0.143 `hierarchical_clustering`

12.0.143.1 Possible use:

- container<agent> **hierarchical_clustering** float —> list
- **hierarchical_clustering** (container<agent> , float) —> list

12.0.143.2   Result:

A tree (list of list) contained groups of agents clustered by distance considering a distance min between two groups.

12.0.143.3   Comment:

use of hierarchical clustering with Minimum for linkage criterion between two groups of agents.

12.0.143.4   Examples:

```
list var0 <- [ag1, ag2, ag3, ag4, ag5] hierarchical_clustering 20.0; // var0 equals for example, can ret
```

12.0.143.5   See also:

simple_clustering_by_distance,

12.0.144   `horizontal`

12.0.144.1   Possible use:

- **horizontal** (`msi.gama.util.GamaMap<java.lang.Object,java.lang.Integer>`) —> `msi.gama.util.tree.GamaNo`

12.0.145   `hsb`

12.0.145.1   Possible use:

- **hsb** (`float, float, float`) —> `rgb`
- **hsb** (`float, float, float, float`) —> `rgb`
- **hsb** (`float, float, float, int`) —> `rgb`

12.0.145.2   Result:

Converts hsb (h=hue, s=saturation, b=brightness) value to Gama color

12.0.145.3   Comment:

h,s and b components should be floating-point values between 0.0 and 1.0 and when used alpha should be an integer (between 0 and 255) or a float (between 0 and 1) . Examples: Red=(0.0,1.0,1.0), Yellow=(0.16,1.0,1.0), Green=(0.33,1.0,1.0), Cyan=(0.5,1.0,1.0), Blue=(0.66,1.0,1.0), Magenta=(0.83,1.0,1.0)

12.0.145.4 Examples:

```
rgb var0 <- hsb (0.0,1.0,1.0); // var0 equals rgb("red")
rgb var1 <- hsb (0.5,1.0,1.0,0.0); // var1 equals rgb("cyan",0)
```

12.0.145.5 See also:

rgb,

12.0.146 hypot

12.0.146.1 Possible use:

- **hypot** (float, float, float, float) —> float

12.0.146.2 Result:

Returns sqrt(x2 +y2) without intermediate overflow or underflow.

12.0.146.3 Special cases:

- If either argument is infinite, then the result is positive infinity. If either argument is NaN and neither argument is infinite, then the result is NaN.

12.0.146.4 Examples:

```
float var0 <- hypot(0,1,0,1); // var0 equals sqrt(2)
```

Chapter 13

Operators (I to M)

13.0.1 IDW

13.0.1.1 Possible use:

- IDW (container<agent>, map<point,float>, int) —> map<agent,float>

13.0.1.2 Result:

Inverse Distance Weighting (IDW) is a type of deterministic method for multivariate interpolation with a known scattered set of points. The assigned values to each geometry are calculated with a weighted average of the values available at the known points. See: http://en.wikipedia.org/wiki/Inverse_distance_weighting Usage: IDW (list of geometries, map of points (key: point, value: value), power parameter)

13.0.1.3 Examples:

map<agent,float> var0 <- IDW([ag1, ag2, ag3, ag4, ag5],[{10,10}::25.0, {10,80}::10.0, {100,10}::15.0],

13.0.2 image_file

13.0.2.1 Possible use:

- **image_file** (string) —> file

13.0.2.2 Result:

Constructs a file of type image. Allowed extensions are limited to tiff, jpg, jpeg, png, pict, bmp

13.0.3 `improved_generator`

13.0.3.1 Possible use:

- **`improved_generator`** (float, float, float, float) —> float

13.0.3.2 Result:

take a x, y, z and a bias parameters and gives a value

13.0.3.3 Examples:

```
float var0 <- improved_generator(2,3,4,253); // var0 equals 10.2
```

13.0.4 `in`

13.0.4.1 Possible use:

- unknown **in** container —> bool
- **in** (unknown , container) —> bool
- string **in** string —> bool
- **in** (string , string) —> bool

13.0.4.2 Result:

true if the right operand contains the left operand, false otherwise

13.0.4.3 Comment:

the definition of in depends on the container

13.0.4.4 Special cases:

- if the right operand is nil or empty, in returns false

- if both operands are strings, returns true if the left-hand operand patterns is included in to the right-hand string;

13.0.4.5 Examples:

```
bool var0 <- 2 in [1,2,3,4,5,6]; // var0 equals true
bool var1 <- 7 in [1,2,3,4,5,6]; // var1 equals false
bool var2 <- 3 in [1::2, 3::4, 5::6]; // var2 equals false
bool var3 <- 6 in [1::2, 3::4, 5::6]; // var3 equals true
bool var4 <-  'bc' in 'abcded'; // var4 equals true
```

contains,

13.0.5   `in_degree_of`

13.0.5.1   Possible use:

- graph **in_degree_of** unknown —> int
- **in_degree_of** (graph , unknown) —> int

13.0.5.2   Result:

returns the in degree of a vertex (right-hand operand) in the graph given as left-hand operand.

13.0.5.3   Examples:

```
int var1 <- graphFromMap in_degree_of (node(3)); // var1 equals 2
```

13.0.5.4   See also:

out_degree_of, degree_of,

13.0.6   `in_edges_of`

13.0.6.1   Possible use:

- graph **in_edges_of** unknown —> list
- **in_edges_of** (graph , unknown) —> list

13.0.6.2   Result:

returns the list of the in-edges of a vertex (right-hand operand) in the graph given as left-hand operand.

13.0.6.3   Examples:

```
list var1 <- graphFromMap in_edges_of node({12,45}); // var1 equals [LineString]
```

13.0.6.4   See also:

out_edges_of,

13.0.7 `incomplete_beta`

13.0.7.1 Possible use:

- `incomplete_beta` (float, float, float) —> `float`

13.0.7.2 Result:

Returns the regularized integral of the beta function with arguments a and b, from zero to x.

13.0.8 `incomplete_gamma`

13.0.8.1 Possible use:

- `float` **`incomplete_gamma`** `float` —> `float`
- **`incomplete_gamma`** (float , float) —> `float`

13.0.8.2 Result:

Returns the regularized integral of the Gamma function with argument a to the integration end point x.

13.0.9 `incomplete_gamma_complement`

13.0.9.1 Possible use:

- `float` **`incomplete_gamma_complement`** `float` —> `float`
- **`incomplete_gamma_complement`** (float , float) —> `float`

13.0.9.2 Result:

Returns the complemented regularized incomplete Gamma function of the argument a and integration start point x.

13.0.10 `indented_by`

13.0.10.1 Possible use:

- `string` **`indented_by`** `int` —> `string`
- **`indented_by`** (string , int) —> `string`

13.0.10.2 Result:

Converts a (possibly multiline) string by indenting it by a number – specified by the second operand – of tabulations to the right

---

13.0.11 `index_by`

13.0.11.1 Possible use:

- container **index_by** any expression —> map
- **index_by** (container , any expression) —> map

13.0.11.2 Result:

produces a new map from the evaluation of the right-hand operand for each element of the left-hand operand

13.0.11.3 Special cases:

- if the left-hand operand is nil, index_by throws an error. If the operation results in duplicate keys, only the first value corresponding to the key is kept

13.0.11.4 Examples:

```
map var0 <- [1,2,3,4,5,6,7,8] index_by (each - 1); // var0 equals [0::1, 1::2, 2::3, 3::4, 4::5, 5::6,
```

13.0.12 `index_of`

13.0.12.1 Possible use:

- map **index_of** unknown —> unknown
- **index_of** (map , unknown) —> unknown
- species **index_of** unknown —> int
- **index_of** (species , unknown) —> int
- string **index_of** string —> int
- **index_of** (string , string) —> int
- matrix **index_of** unknown —> point
- **index_of** (matrix , unknown) —> point
- list **index_of** unknown —> int
- **index_of** (list , unknown) —> int

13.0.12.2 Result:

the index of the first occurence of the right operand in the left operand container the index of the first occurence of the right operand in the left operand container

13.0.12.3   Comment:

The definition of index_of and the type of the index depend on the container

13.0.12.4   Special cases:

- if the left operand is a map, index_of returns the index of a value or nil if the value is not mapped

- if the left operator is a species, returns the index of an agent in a species. If the argument is not an agent of this species, returns -1. Use int(agent) instead

- if both operands are strings, returns the index within the left-hand string of the first occurrence of the given right-hand string

```
int var1 <-  "abcabcabc" index_of "ca"; // var1 equals 2
```

- if the left operand is a matrix, index_of returns the index as a point

```
point var2 <- matrix([[1,2,3],[4,5,6]]) index_of 4; // var2 equals {1.0,0.0}
```

- if the left operand is a list, index_of returns the index as an integer

```
int var3 <- [1,2,3,4,5,6] index_of 4; // var3 equals 3
int var4 <- [4,2,3,4,5,4] index_of 4; // var4 equals 0
```

13.0.12.5   Examples:

```
unknown var0 <- [1::2, 3::4, 5::6] index_of 4; // var0 equals 3
```

13.0.12.6   See also:

at, last_index_of,

———————————————————————

13.0.13   `inside`

13.0.13.1   Possible use:

- container<agent> **inside** geometry —> list<geometry>
- **inside** (container<agent> , geometry) —> list<geometry>

13.0.13.2   Result:

A list of agents or geometries among the left-operand list, species or meta-population (addition of species), covered by the operand (casted as a geometry).

13.0.13.3 Examples:

```
list<geometry> var0 <- [ag1, ag2, ag3] inside(self); // var0 equals the agents among ag1, ag2 and ag3 th
list<geometry> var1 <- (species1 + species2) inside (self); // var1 equals the agents among species spe
```

13.0.13.4 See also:

neighbors_at, neighbors_of, closest_to, overlapping, agents_overlapping, agents_inside, agent_closest_to,

---

13.0.14 `int`

13.0.14.1 Possible use:

- **int** (any) —> int

13.0.14.2 Result:

Casts the operand into the type int

13.0.15 `inter`

13.0.15.1 Possible use:

- container **inter** container —> list
- **inter** (container , container) —> list
- geometry **inter** geometry —> geometry
- **inter** (geometry , geometry) —> geometry

13.0.15.2 Result:

the intersection of the two operands A geometry resulting from the intersection between the two geometries

13.0.15.3 Comment:

both containers are transformed into sets (so without duplicated element, cf. remove_deplicates operator)
before the set intersection is computed.

13.0.15.4 Special cases:

- if an operand is a graph, it will be transformed into the set of its nodes

- returns nil if one of the operands is nil

- if an operand is a map, it will be transformed into the set of its values

```
list var0 <- [1::2, 3::4, 5::6] inter [2,4]; // var0 equals [2,4]
list var1 <- [1::2, 3::4, 5::6] inter [1,3]; // var1 equals []
```

- if an operand is a matrix, it will be transformed into the set of the lines

```
list var2 <- matrix([[3,2,1],[4,5,4]]) inter [3,4]; // var2 equals [3,4]
```

13.0.15.5 Examples:

```
list var3 <- [1,2,3,4,5,6] inter [2,4]; // var3 equals [2,4]
list var4 <- [1,2,3,4,5,6] inter [0,8]; // var4 equals []
geometry var5 <- square(10) inter circle(5); // var5 equals circle(5)
```

13.0.15.6 See also:

remove_duplicates, union, +, -,

13.0.16 interleave

13.0.16.1 Possible use:

- **interleave** (container) —> list

13.0.16.2 Result:

a new list containing the interleaved elements of the containers contained in the operand

13.0.16.3 Comment:

the operand should be a list of lists of elements. The result is a list of elements.

13.0.16.4 Examples:

```
list var0 <- interleave([1,2,4,3,5,7,6,8]); // var0 equals [1,2,4,3,5,7,6,8]
list var1 <- interleave([['e11','e12','e13'],['e21','e22','e23'],['e31','e32','e33']]); // var1 equals
```

13.0.17 internal_at

13.0.17.1 Possible use:

- agent **internal_at** list —> unknown
- **internal_at** (agent , list) —> unknown
- container<KeyType,ValueType> **internal_at** list<KeyType> —> ValueType

- **internal_at** (container<KeyType,ValueType> , list<KeyType>) —> ValueType
- geometry **internal_at** list —> unknown
- **internal_at** (geometry , list) —> unknown

13.0.17.2 Result:

For internal use only. Corresponds to the implementation, for agents, of the access to containers with [index] For internal use only. Corresponds to the implementation of the access to containers with [index] For internal use only. Corresponds to the implementation, for geometries, of the access to containers with [index]

13.0.17.3 See also:

at,

13.0.18 internal_integrated_value

13.0.18.1 Possible use:

- any expression **internal_integrated_value** any expression —> list
- **internal_integrated_value** (any expression , any expression) —> list

13.0.18.2 Result:

For internal use only. Corresponds to the implementation, for agents, of the access to containers with [index]

13.0.19 internal_zero_order_equation

13.0.19.1 Possible use:

- **internal_zero_order_equation** (any expression) —> float

13.0.19.2 Result:

An internal placeholder function

13.0.20 intersection

Same signification as inter

13.0.21 intersects

13.0.21.1 Possible use:

- geometry **intersects** geometry —> bool
- **intersects** (geometry , geometry) —> bool

13.0.21.2 Result:

A boolean, equal to true if the left-geometry (or agent/point) intersects the right-geometry (or agent/point).

13.0.21.3 Special cases:

- if one of the operand is null, returns false.

13.0.21.4 Examples:

```
bool var0 <- square(5) intersects {10,10}; // var0 equals false
```

13.0.21.5 See also:

disjoint_from, crosses, overlaps, partially_overlaps, touches,

---

13.0.22 inverse

13.0.22.1 Possible use:

- **inverse** (matrix) —> matrix<float>

13.0.22.2 Result:

The inverse matrix of the given matrix. If no inverse exists, returns a matrix that has properties that resemble that of an inverse.

13.0.22.3 Examples:

```
matrix<float> var0 <- inverse(matrix([[4,3],[3,2]])); // var0 equals matrix([[-2.0,3.0],[3.0,-4.0]])
```

13.0.23 inverse_distance_weighting

Same signification as IDW

13.0.24 `is`

13.0.24.1 Possible use:

- unknown **is** any expression —> bool
- **is** (unknown , any expression) —> bool

13.0.24.2 Result:

returns true if the left operand is of the right operand type, false otherwise

13.0.24.3 Examples:

```
bool var0 <- 0 is int; // var0 equals true
bool var1 <- an_agent is node; // var1 equals true
bool var2 <- 1 is float; // var2 equals false
```

13.0.25 `is_csv`

13.0.25.1 Possible use:

- **is_csv** (any) —> bool

13.0.25.2 Result:

Tests whether the operand is a csv file.

13.0.26 `is_dxf`

13.0.26.1 Possible use:

- **is_dxf** (any) —> bool

13.0.26.2 Result:

Tests whether the operand is a dxf file.

13.0.27 `is_error`

13.0.27.1 Possible use:

- **is_error** (any expression) —> bool

13.0.27.2   Result:

Returns whether or not the argument raises an error when evaluated

---

13.0.28   `is_finite`

13.0.28.1   Possible use:

- **`is_finite`** (float) —> `bool`

13.0.28.2   Result:

Returns whether the argument is a finite number or not

13.0.28.3   Examples:

```
bool var0 <- is_finite(4.66); // var0 equals true
bool var1 <- is_finite(#infinity); // var1 equals false
```

13.0.29   `is_gaml`

13.0.29.1   Possible use:

- **`is_gaml`** (any) —> `bool`

13.0.29.2   Result:

Tests whether the operand is a gaml file.

13.0.30   `is_geojson`

13.0.30.1   Possible use:

- **`is_geojson`** (any) —> `bool`

13.0.30.2   Result:

Tests whether the operand is a geojson file.

13.0.31 `is_gif`

13.0.31.1 Possible use:

- **`is_gif`** (any) —> `bool`

13.0.31.2 Result:

Tests whether the operand is a gif file.

13.0.32 `is_gml`

13.0.32.1 Possible use:

- **`is_gml`** (any) —> `bool`

13.0.32.2 Result:

Tests whether the operand is a gml file.

13.0.33 `is_grid`

13.0.33.1 Possible use:

- **`is_grid`** (any) —> `bool`

13.0.33.2 Result:

Tests whether the operand is a grid file.

13.0.34 `is_image`

13.0.34.1 Possible use:

- **`is_image`** (any) —> `bool`

13.0.34.2 Result:

Tests whether the operand is a image file.

13.0.35 is_json

13.0.35.1 Possible use:

- **is_json** (any) —> bool

13.0.35.2 Result:

Tests whether the operand is a json file.

13.0.36 is_number

13.0.36.1 Possible use:

- **is_number** (float) —> bool
- **is_number** (string) —> bool

13.0.36.2 Result:

Returns whether the argument is a real number or not tests whether the operand represents a numerical value

13.0.36.3 Comment:

Note that the symbol . should be used for a float value (a string with , will not be considered as a numeric value). Symbols e and E are also accepted. A hexadecimal value should begin with #.

13.0.36.4 Examples:

```
bool var0 <- is_number(4.66); // var0 equals true
bool var1 <- is_number(#infinity); // var1 equals true
bool var2 <- is_number(#nan); // var2 equals false
bool var3 <- is_number("test"); // var3 equals false
bool var4 <- is_number("123.56"); // var4 equals true
bool var5 <- is_number("-1.2e5"); // var5 equals true
bool var6 <- is_number("1,2"); // var6 equals false
bool var7 <- is_number("#12FA"); // var7 equals true
```

13.0.37 is_obj

13.0.37.1 Possible use:

- **is_obj** (any) —> bool

13.0.37.2 Result:

Tests whether the operand is a obj file.

13.0.38 `is_osm`

13.0.38.1 Possible use:

- **is_osm** (any) —> bool

13.0.38.2 Result:

Tests whether the operand is a osm file.

13.0.39 `is_pgm`

13.0.39.1 Possible use:

- **is_pgm** (any) —> bool

13.0.39.2 Result:

Tests whether the operand is a pgm file.

13.0.40 `is_property`

13.0.40.1 Possible use:

- **is_property** (any) —> bool

13.0.40.2 Result:

Tests whether the operand is a property file.

13.0.41 `is_R`

13.0.41.1 Possible use:

- **is_R** (any) —> bool

13.0.41.2 Result:

Tests whether the operand is a R file.

13.0.42 `is_saved_simulation`

13.0.42.1 Possible use:

- **`is_saved_simulation`** (any) —> `bool`

13.0.42.2 Result:

Tests whether the operand is a saved_simulation file.

13.0.43 `is_shape`

13.0.43.1 Possible use:

- **`is_shape`** (any) —> `bool`

13.0.43.2 Result:

Tests whether the operand is a shape file.

13.0.44 `is_skill`

13.0.44.1 Possible use:

- unknown **`is_skill`** `string` —> `bool`
- **`is_skill`** (unknown , `string`) —> `bool`

13.0.44.2 Result:

returns true if the left operand is an agent whose species implements the right-hand skill name

13.0.44.3 Examples:

```
bool var0 <- agentA is_skill 'moving'; // var0 equals true
```

13.0.45 `is_svg`

13.0.45.1 Possible use:

- **is_svg** (any) —> bool

13.0.45.2 Result:

Tests whether the operand is a svg file.

13.0.46 `is_text`

13.0.46.1 Possible use:

- **is_text** (any) —> bool

13.0.46.2 Result:

Tests whether the operand is a text file.

13.0.47 `is_threeds`

13.0.47.1 Possible use:

- **is_threeds** (any) —> bool

13.0.47.2 Result:

Tests whether the operand is a threeds file.

13.0.48 `is_URL`

13.0.48.1 Possible use:

- **is_URL** (any) —> bool

13.0.48.2 Result:

Tests whether the operand is a URL file.

13.0.49 `is_warning`

13.0.49.1 Possible use:

- **`is_warning`** (any expression) —> `bool`

13.0.49.2 Result:

Returns whether or not the argument raises a warning when evaluated

---

13.0.50 `is_xml`

13.0.50.1 Possible use:

- **`is_xml`** (any) —> `bool`

13.0.50.2 Result:

Tests whether the operand is a xml file.

13.0.51 `json_file`

13.0.51.1 Possible use:

- **`json_file`** (string) —> `file`

13.0.51.2 Result:

Constructs a file of type json. Allowed extensions are limited to json

---

13.0.52 `kappa`

13.0.52.1 Possible use:

- **`kappa`** (list, list, list) —> `float`
- **`kappa`** (list, list, list, list) —> `float`

13.0.52.2 Result:

kappa indicator for 2 map comparisons: kappa(list_vals1,list_vals2,categories, weights). Reference: Cohen, J. A coefficient of agreement for nominal scales. Educ. Psychol. Meas. 1960, 20. kappa indicator for 2 map comparisons: kappa(list_vals1,list_vals2,categories). Reference: Cohen, J. A coefficient of agreement for nominal scales. Educ. Psychol. Meas. 1960, 20.

13.0.52.3 Examples:

```
kappa([cat1,cat1,cat2,cat3,cat2],[cat2,cat1,cat2,cat1,cat2],[cat1,cat2,cat3], [1.0, 2.0, 3.0, 1.0, 5.0]
float var2 <- kappa([1,3,5,1,5],[1,1,1,1,5],[1,3,5]); // var2 equals the similarity between 0 and 1
float var3 <- kappa([1,1,1,1,5],[1,1,1,1,5],[1,3,5]); // var3 equals 1.0
```

13.0.53 `kappa_sim`

13.0.53.1 Possible use:

- **kappa_sim** (list, list, list, list) —> float
- **kappa_sim** (list, list, list, list, list) —> float

13.0.53.2 Result:

kappa simulation indicator for 2 map comparisons: kappa(list_valsInits,list_valsObs,list_valsSim, categories). Reference: van Vliet, J., Bregt, A.K. & Hagen-Zanker, A. (2011). Revisiting Kappa to account for change in the accuracy assessment of land-use change models, Ecological Modelling 222(8). kappa simulation indicator for 2 map comparisons: kappa(list_valsInits,list_valsObs,list_valsSim, categories, weights). Reference: van Vliet, J., Bregt, A.K. & Hagen-Zanker, A. (2011). Revisiting Kappa to account for change in the accuracy assessment of land-use change models, Ecological Modelling 222(8)

13.0.53.3 Examples:

```
kappa([cat1,cat1,cat2,cat2,cat2],[cat2,cat1,cat2,cat1,cat3],[cat2,cat1,cat2,cat3,cat3], [cat1,cat2,cat3]
```

13.0.54 `kmeans`

13.0.54.1 Possible use:

- list **kmeans** int —> list<list>
- **kmeans** (list , int) —> list<list>
- **kmeans** (list, int, int) —> list<list>

13.0.54.2 Result:

returns the list of clusters (list of instance indices) computed with the kmeans++ algorithm from the first operand data according to the number of clusters to split the data into (k) and the maximum number of iterations to run the algorithm for (If negative, no maximum will be used) (maxIt). Usage: kmeans(data,k,maxit) returns the list of clusters (list of instance indices) computed with the kmeans++ algorithm from the first operand data according to the number of clusters to split the data into (k). Usage: kmeans(data,k)

13.0.54.3 Special cases:

- if the lengths of two vectors in the right-hand aren't equal, returns 0

- if the lengths of two vectors in the right-hand aren't equal, returns 0

13.0.54.4 Examples:

```
kmeans ([[2,4,5], [3,8,2], [1,1,3], [4,3,4]],2,10)
list<list> var1 <- kmeans ([[2,4,5], [3,8,2], [1,1,3], [4,3,4]],2); // var1 equals []
```

13.0.55 kml

13.0.55.1 Possible use:

- **kml** (any) —> kml

13.0.55.2 Result:

Casts the operand into the type kml

13.0.56 kurtosis

13.0.56.1 Possible use:

- **kurtosis** (list) —> float

13.0.56.2 Result:

returns kurtosis value computed from the operand list of values

13.0.56.3 Special cases:

- if the length of the list is lower than 3, returns NaN

13.0.56.4 Examples:

```
float var0 <- kurtosis ([1,2,3,4,5]); // var0 equals 1.0
```

13.0.57 `kurtosis`

13.0.57.1 Possible use:

- **kurtosis** (container) —> float
- float **kurtosis** float —> float
- **kurtosis** (float , float) —> float

13.0.57.2 Result:

Returns the kurtosis (aka excess) of a data sequence Returns the kurtosis (aka excess) of a data sequence

---

13.0.58 `last`

13.0.58.1 Possible use:

- **last** (string) —> string
- **last** (container<KeyType,ValueType>) —> ValueType
- int **last** container —> list
- **last** (int , container) —> list

13.0.58.2 Result:

the last element of the operand

13.0.58.3 Comment:

the last operator behavior depends on the nature of the operand

13.0.58.4 Special cases:

- if it is a map, last returns the value of the last pair (in insertion order)

- if it is a file, last returns the last element of the content of the file (that is also a container)

- if it is a population, last returns the last agent of the population

- if it is a graph, last returns a list containing the last edge created

- if it is a matrix, last returns the element at {length-1,length-1} in the matrix

- for a matrix of int or float, it will return 0 if the matrix is empty

- for a matrix of object or geometry, it will return nil if the matrix is empty

- if it is a string, last returns a string composed of its last character, or an empty string if the operand is empty

```
string var0 <- last ('abce'); // var0 equals 'e'
```

- if it is a list, last returns the last element of the list, or nil if the list is empty

```
int var1 <- last ([1, 2, 3]); // var1 equals 3
```

13.0.58.5   See also:

first,

13.0.59   `last_index_of`

13.0.59.1   Possible use:

- string **last_index_of** string —> int
- **last_index_of** (string , string) —> int
- matrix **last_index_of** unknown —> point
- **last_index_of** (matrix , unknown) —> point
- species **last_index_of** unknown —> int
- **last_index_of** (species , unknown) —> int
- list **last_index_of** unknown —> int
- **last_index_of** (list , unknown) —> int
- map **last_index_of** unknown —> unknown
- **last_index_of** (map , unknown) —> unknown

13.0.59.2   Result:

the index of the last occurence of the right operand in the left operand container

13.0.59.3   Comment:

The definition of last_index_of and the type of the index depend on the container

13.0.59.4   Special cases:

- if the left operand is a species, the last index of an agent is the same as its index

- if both operands are strings, returns the index within the left-hand string of the rightmost occurrence of the given right-hand string

```
int var0 <- "abcabcabc" last_index_of "ca"; // var0 equals 5
```

- if the left operand is a matrix, last_index_of returns the index as a point

```
point var1 <- matrix([[1,2,3],[4,5,4]]) last_index_of 4; // var1 equals {1.0,2.0}
```

- if the left operand is a list, last_index_of returns the index as an integer

```
int var2 <- [1,2,3,4,5,6] last_index_of 4; // var2 equals 3
int var3 <- [4,2,3,4,5,4] last_index_of 4; // var3 equals 5
```

- if the left operand is a map, last_index_of returns the index as an int (the key of the pair)

```
unknown var4 <- [1::2, 3::4, 5::4] last_index_of 4; // var4 equals 5
```

13.0.59.5   See also:

at, index_of, last_index_of,

13.0.60   `last_of`

Same signification as last

13.0.61   `last_with`

13.0.61.1   Possible use:

- container **last_with** any expression —> unknown
- **last_with** (container , any expression) —> unknown

13.0.61.2   Result:

the last element of the left-hand operand that makes the right-hand operand evaluate to true.

13.0.61.3   Comment:

in the right-hand operand, the keyword each can be used to represent, in turn, each of the right-hand operand elements.

13.0.61.4   Special cases:

- if the left-hand operand is nil, last_with throws an error.

- If there is no element that satisfies the condition, it returns nil

- if the left-operand is a map, the keyword each will contain each value

```
unknown var4 <- [1::2, 3::4, 5::6] last_with (each >= 4); // var4 equals 6
unknown var5 <- [1::2, 3::4, 5::6].pairs last_with (each.value >= 4); // var5 equals (5::6)
```

13.0.61.5   Examples:

```
unknown var0 <- [1,2,3,4,5,6,7,8] last_with (each > 3); // var0 equals 8
unknown var2 <- g2 last_with (length(g2 out_edges_of each) = 0 ); // var2 equals node11
unknown var3 <- (list(node) last_with (round(node(each).location.x) > 32); // var3 equals node3
```

13.0.61.6   See also:

group_by, first_with, where,

13.0.62   `layout`

13.0.62.1   Possible use:

- graph **layout** string —> graph
- **layout** (graph , string) —> graph
- **layout** (graph, string, int) —> graph
- **layout** (graph, string, int, map<string,unknown>) —> graph

13.0.62.2   Result:

layouts a GAMA graph.

13.0.63   `length`

13.0.63.1   Possible use:

- **length** (container<KeyType,ValueType>) —> int
- **length** (string) —> int

13.0.63.2   Result:

the number of elements contained in the operand

13.0.63.3   Comment:

the length operator behavior depends on the nature of the operand

13.0.63.4   Special cases:

- if it is a population, length returns number of agents of the population

- if it is a graph, length returns the number of vertexes or of edges (depending on the way it was created)

- if it is a list or a map, length returns the number of elements in the list or map

```
int var0 <- length([12,13]); // var0 equals 2
int var1 <- length([]); // var1 equals 0
```

- if it is a matrix, length returns the number of cells

```
int var2 <- length(matrix([["c11","c12","c13"],["c21","c22","c23"]])); // var2 equals 6
```

- if it is a string, length returns the number of characters

```
int var3 <- length ('I am an agent'); // var3 equals 13
```

13.0.64 `lgamma`

Same signification as log_gamma

13.0.65 `line`

13.0.65.1 Possible use:

- **line** (container<geometry>) —> geometry
- container<geometry> **line** float —> geometry
- **line** (container<geometry> , float) —> geometry

13.0.65.2 Result:

A polyline geometry from the given list of points. A polyline geometry from the given list of points represented as a cylinder of radius r.

13.0.65.3 Special cases:

- if the operand is nil, returns the point geometry {0,0}

- if the operand is composed of a single point, returns a point geometry.

- if the operand is nil, returns the point geometry {0,0}

- if the operand is composed of a single point, returns a point geometry.

- if a radius is added, the given list of points represented as a cylinder of radius r

```
geometry var1 <- polyline({{0,0}, {0,10}, {10,10}, {10,0}},0.2); // var1 equals a polyline geometry comp
```

13.0.65.4 Examples:

```
geometry var0 <- polyline({{0,0}, {0,10}, {10,10}, {10,0}}); // var0 equals a polyline geometry composed
```

13.0.65.5 See also:

around, circle, cone, link, norm, point, polygone, rectangle, square, triangle,

---

13.0.66 `link`

13.0.66.1 Possible use:

- `geometry` **`link`** `geometry` —> `geometry`
- **`link`** `(geometry , geometry)` —> `geometry`

13.0.66.2 Result:

A dynamic line geometry between the location of the two operands

13.0.66.3 Comment:

The geometry of the link is a line between the locations of the two operands, which is built and maintained dynamically

13.0.66.4 Special cases:

- if one of the operands is nil, link returns a point geometry at the location of the other. If both are null, it returns a point geometry at {0,0}

13.0.66.5 Examples:

```
geometry var0 <- link (geom1,geom2); // var0 equals a link geometry between geom1 and geom2.
```

13.0.66.6 See also:

around, circle, cone, line, norm, point, polygon, polyline, rectangle, square, triangle,

---

13.0.67 `list`

13.0.67.1 Possible use:

- **`list`** `(any)` —> `list`

13.0.67.2 Result:

Casts the operand into the type list

13.0.68 `list_with`

13.0.68.1 Possible use:

- int **list_with** any expression —> list
- **list_with** (int , any expression) —> list

13.0.68.2 Result:

creates a list with a size provided by the first operand, and filled with the second operand

13.0.68.3 Comment:

Note that the right operand should be positive, and that the second one is evaluated for each position in the list.

13.0.68.4 See also:

list,

13.0.69 `ln`

13.0.69.1 Possible use:

- **ln** (float) —> float
- **ln** (int) —> float

13.0.69.2 Result:

Returns the natural logarithm (base e) of the operand.

13.0.69.3 Special cases:

- an exception is raised if the operand is less than zero.

13.0.69.4 Examples:

```
float var0 <- ln(exp(1)); // var0 equals 1.0
float var1 <- ln(1); // var1 equals 0.0
```

13.0.69.5 See also:

exp,

13.0.70 `load_graph_from_file`

13.0.70.1 Possible use:

- `load_graph_from_file` (string) —> graph
- string `load_graph_from_file` string —> graph
- `load_graph_from_file` (string , string) —> graph
- string `load_graph_from_file` file —> graph
- `load_graph_from_file` (string , file) —> graph
- `load_graph_from_file` (string, species, species) —> graph
- `load_graph_from_file` (string, string, species, species) —> graph
- `load_graph_from_file` (string, file, species, species) —> graph
- `load_graph_from_file` (string, string, species, species, bool) —> graph

13.0.70.2 Result:

loads a graph from a file returns a graph loaded from a given file encoded into a given format. The last boolean parameter indicates whether the resulting graph will be considered as spatial or not by GAMA

13.0.70.3 Comment:

Available formats: "pajek": Pajek (Slovene word for Spider) is a program, for Windows, for analysis and visualization of large networks. See: http://pajek.imfm.si/doku.php?id=pajek for more details."lgl": LGL is a compendium of applications for making the visualization of large networks and trees tractable. See: http://lgl.sourceforge.net/ for more details."dot": DOT is a plain text graph description language. It is a simple way of describing graphs that both humans and computer programs can use. See: http://en.wikipedia. org/wiki/DOT_language for more details."edge": This format is a simple text file with numeric vertex ids defining the edges."gexf": GEXF (Graph Exchange XML Format) is a language for describing complex networks structures, their associated data and dynamics. Started in 2007 at Gephi project by different actors, deeply involved in graph exchange issues, the gexf specifications are mature enough to claim being both extensible and open, and suitable for real specific applications. See: http://gexf.net/format/ for more details."graphml": GraphML is a comprehensive and easy-to-use file format for graphs based on XML. See: http://graphml.graphdrawing.org/ for more details."tlp" or "tulip": TLP is the Tulip software graph format. See: http://tulip.labri.fr/TulipDrupal/?q=tlp-file-format for more details. "ncol": This format is used by the Large Graph Layout progra. It is simply a symbolic weighted edge list. It is a simple text file with one edge per line. An edge is defined by two symbolic vertex names separated by whitespace. (The symbolic vertex names themselves cannot contain whitespace.) They might followed by an optional number, this will be the weight of the edge. See: http://bioinformatics.icmb.utexas.edu/lgl for more details.The map operand should includes following elements:Available formats: "pajek": Pajek (Slovene word for Spider) is a program, for Windows, for analysis and visualization of large networks. ```

- "format": the format of the file, "file": the file containing the network, "edges_species": the species of edges, "vertices_specy": the species of vertices

```
graph<myVertexSpecy,myEdgeSpecy> myGraph <- load_graph_from_file(        "pajek",        "example
```

13.0.70.5 Examples:

```
graph<myVertexSpecy,myEdgeSpecy> myGraph <- load_graph_from_file(        "pajek",        "./examp
```

13.0.71 load_shortest_paths

13.0.71.1 Possible use:

- graph **load_shortest_paths** matrix —> graph
- **load_shortest_paths** (graph , matrix) —> graph

13.0.71.2 Result:

put in the graph cache the computed shortest paths contained in the matrix (rows: source, columns: target)

13.0.71.3 Examples:

```
graph var0 <- load_shortest_paths(shortest_paths_matrix); // var0 equals return my_graph with all the sl
```

13.0.72 `load_sub_model`

13.0.72.1 Possible use:

- string **load_sub_model** string —> msi.gama.kernel.experiment.IExperimentAgent
- **load_sub_model** (string , string) —> msi.gama.kernel.experiment.IExperimentAgent

13.0.72.2 Result:

Load a submodel

13.0.72.3 Comment:

loaded submodel

13.0.73 `log`

13.0.73.1 Possible use:

- **log** (int) —> float
- **log** (float) —> float

13.0.73.2 Result:

Returns the logarithm (base 10) of the operand.

13.0.73.3 Special cases:

- an exception is raised if the operand is equals or less than zero.

13.0.73.4 Examples:

```
float var0 <- log(1); // var0 equals 0.0
float var1 <- log(10); // var1 equals 1.0
```

13.0.73.5   See also:

ln,

13.0.74   `log_gamma`

13.0.74.1   Possible use:

- **`log_gamma`** (float) —> float

13.0.74.2   Result:

Returns the log of the value of the Gamma function at x.

13.0.75   `lower_case`

13.0.75.1   Possible use:

- **`lower_case`** (string) —> string

13.0.75.2   Result:

Converts all of the characters in the string operand to lower case

13.0.75.3   Examples:

```
string var0 <- lower_case("Abc"); // var0 equals 'abc'
```

13.0.75.4   See also:

upper_case,

13.0.76   `main_connected_component`

13.0.76.1   Possible use:

- **`main_connected_component`** (graph) —> graph

13.0.76.2   Result:

returns the sub-graph corresponding to the main connected components of the graph

13.0.76.3   Examples:

```
graph var0 <- main_connected_component(my_graph); // var0 equals the sub-graph corresponding to the mai
```

13.0.76.4   See also:

connected_components_of,

13.0.77   map

13.0.77.1   Possible use:

- **map** (any) —> map

13.0.77.2   Result:

Casts the operand into the type map

13.0.78   masked_by

13.0.78.1   Possible use:

- geometry **masked_by** container<geometry> —> geometry
- **masked_by** (geometry , container<geometry>) —> geometry
- **masked_by** (geometry, container<geometry>, int) —> geometry

13.0.78.2   Examples:

```
geometry var0 <- perception_geom masked_by obstacle_list; // var0 equals the geometry representing the
geometry var1 <- perception_geom masked_by obstacle_list; // var1 equals the geometry representing the
```

13.0.79   material

13.0.79.1   Possible use:

- float **material** float —> msi.gama.util.GamaMaterial
- **material** (float , float) —> msi.gama.util.GamaMaterial

13.0.79.2   Result:

Returns

13.0.79.3 Examples:

13.0.79.4 See also:

,

13.0.80 `material`

13.0.80.1 Possible use:

- `material` (any) —> `material`

13.0.80.2 Result:

Casts the operand into the type material

13.0.81 `matrix`

13.0.81.1 Possible use:

- `matrix` (any) —> `matrix`

13.0.81.2 Result:

Casts the operand into the type matrix

13.0.82 `matrix_with`

13.0.82.1 Possible use:

- `point` **`matrix_with`** `any expression` —> `matrix`
- `matrix_with` (`point` , `any expression`) —> `matrix`

13.0.82.2 Result:

creates a matrix with a size provided by the first operand, and filled with the second operand

13.0.82.3 Comment:

Note that both components of the right operand point should be positive, otherwise an exception is raised.

13.0.82.4   See also:

matrix, as_matrix,

13.0.83   `max`

13.0.83.1   Possible use:

- **max** (container) —> unknown

13.0.83.2   Result:

the maximum element found in the operand

13.0.83.3   Comment:

the max operator behavior depends on the nature of the operand

13.0.83.4   Special cases:

- if it is a population of a list of other type: max transforms all elements into integer and returns the maximum of them

- if it is a map, max returns the maximum among the list of all elements value

- if it is a file, max returns the maximum of the content of the file (that is also a container)

- if it is a graph, max returns the maximum of the list of the elements of the graph (that can be the list of edges or vertexes depending on the graph)

- if it is a matrix of int, float or object, max returns the maximum of all the numerical elements (thus all elements for integer and float matrices)

- if it is a matrix of geometry, max returns the maximum of the list of the geometries

- if it is a matrix of another type, max returns the maximum of the elements transformed into float

- if it is a list of int of float, max returns the maximum of all the elements

```
unknown var0 <- max ([100, 23.2, 34.5]); // var0 equals 100.0
```

- if it is a list of points: max returns the maximum of all points as a point (i.e. the point with the greatest coordinate on the x-axis, in case of equality the point with the greatest coordinate on the y-axis is chosen. If all the points are equal, the first one is returned.)

```
unknown var1 <- max([{1.0,3.0},{3.0,5.0},{9.0,1.0},{7.0,8.0}]); // var1 equals {9.0,1.0}
```

13.0.83.5 See also:

min,

13.0.84 `max_flow_between`

13.0.84.1 Possible use:

- **max_flow_between** (graph, unknown, unknown) —> msi.gama.util.GamaMap<java.lang.Object,java.lang.Double>

13.0.84.2 Result:

The max flow (map in a graph between the source and the sink using Edmonds-Karp algorithm

13.0.84.3 Examples:

```
max_flow_between(my_graph, vertice1, vertice2)
```

13.0.85 `max_of`

13.0.85.1 Possible use:

- container **max_of** any expression —> unknown
- **max_of** (container , any expression) —> unknown

13.0.85.2 Result:

the maximum value of the right-hand expression evaluated on each of the elements of the left-hand operand

13.0.85.3 Comment:

in the right-hand operand, the keyword each can be used to represent, in turn, each of the right-hand operand elements.

13.0.85.4 Special cases:

- As of GAMA 1.6, if the left-hand operand is nil or empty, max__of throws an error

- if the left-operand is a map, the keyword each will contain each value

```
unknown var4 <- [1::2, 3::4, 5::6] max_of (each + 3); // var4 equals 9
```

13.0.85.5   Examples:

```
unknown var0 <- [1,2,4,3,5,7,6,8] max_of (each * 100 ); // var0 equals 800graph g2 <- as_edge_graph([{1
unknown var2 <- g2.vertices max_of (g2 degree_of( each )); // var2 equals 2
unknown var3 <- (list(node) max_of (round(node(each).location.x)); // var3 equals 96
```

13.0.85.6   See also:

min_of,

13.0.86   maximal_cliques_of

13.0.86.1   Possible use:

- **maximal_cliques_of** (graph) —> list<list>

13.0.86.2   Result:

returns the maximal cliques of a graph using the Bron-Kerbosch clique detection algorithm: A clique is maximal if it is impossible to enlarge it by adding another vertex from the graph. Note that a maximal clique is not necessarily the biggest clique in the graph.

13.0.86.3   Examples:

```
graph my_graph <- graph([]);
list<list> var1 <- maximal_cliques_of (my_graph); // var1 equals the list of all the maximal cliques as
```

13.0.86.4   See also:

biggest_cliques_of,

13.0.87   mean

13.0.87.1   Possible use:

- **mean** (container) —> unknown

13.0.87.2   Result:

the mean of all the elements of the operand

13.0.87.3 Comment:

the elements of the operand are summed (see sum for more details about the sum of container elements) and then the sum value is divided by the number of elements.

13.0.87.4 Special cases:

- if the container contains points, the result will be a point. If the container contains rgb values, the result will be a rgb color

13.0.87.5 Examples:

```
unknown var0 <- mean ([4.5, 3.5, 5.5, 7.0]); // var0 equals 5.125
```

13.0.87.6 See also:

sum,

13.0.88 `mean_deviation`

13.0.88.1 Possible use:

- `mean_deviation` (container) —> `float`

13.0.88.2 Result:

the deviation from the mean of all the elements of the operand. See Mean_deviation for more details.

13.0.88.3 Comment:

The operator casts all the numerical element of the list into float. The elements that are not numerical are discarded.

13.0.88.4 Examples:

```
float var0 <- mean_deviation ([4.5, 3.5, 5.5, 7.0]); // var0 equals 1.125
```

13.0.88.5 See also:

mean, standard_deviation,

13.0.89 `mean_of`

13.0.89.1 Possible use:

- container **mean_of** any expression —> unknown
- **mean_of** (container , any expression) —> unknown

13.0.89.2 Result:

the mean of the right-hand expression evaluated on each of the elements of the left-hand operand

13.0.89.3 Comment:

in the right-hand operand, the keyword each can be used to represent, in turn, each of the right-hand operand elements.

13.0.89.4 Special cases:

- if the left-operand is a map, the keyword each will contain each value

```
unknown var1 <- [1::2, 3::4, 5::6] mean_of (each); // var1 equals 4
```

13.0.89.5 Examples:

```
unknown var0 <- [1,2] mean_of (each * 10 ); // var0 equals 15
```

13.0.89.6 See also:

min_of, max_of, sum_of, product_of,

13.0.90 `meanR`

13.0.90.1 Possible use:

- **meanR** (container) —> unknown

13.0.90.2 Result:

returns the mean value of given vector (right-hand operand) in given variable (left-hand operand).

13.0.90.3 Examples:

```
list<int> X <- [2, 3, 1];
int var1 <- meanR(X); // var1 equals 2
```

13.0.91 `median`

13.0.91.1 Possible use:

- **median** (container) —> unknown

13.0.91.2 Result:

the median of all the elements of the operand.

13.0.91.3 Special cases:

- if the container contains points, the result will be a point. If the container contains rgb values, the result will be a rgb color

13.0.91.4 Examples:

```
unknown var0 <- median ([4.5, 3.5, 5.5, 3.4, 7.0]); // var0 equals 4.5
```

13.0.91.5 See also:

mean,

13.0.92 `mental_state`

13.0.92.1 Possible use:

- **mental_state** (any) —> mental_state

13.0.92.2 Result:

Casts the operand into the type mental_state

13.0.93 `message`

13.0.93.1 Possible use:

- **message** (unknown) —> msi.gama.extensions.messaging.GamaMessage

13.0.93.2 Result:

to be added

13.0.94 `milliseconds_between`

13.0.94.1 Possible use:

- date **`milliseconds_between`** date —> float
- **`milliseconds_between`** (date , date) —> float

13.0.94.2 Result:

Provide the exact number of milliseconds between two dates. This number can be positive or negative (if the second operand is smaller than the first one)

13.0.94.3 Examples:

```
float var0 <- milliseconds_between(date('2000-01-01'), date('2000-02-01')); // var0 equals 2.6784E9
```

13.0.95 `min`

13.0.95.1 Possible use:

- **`min`** (container) —> unknown

13.0.95.2 Result:

the minimum element found in the operand.

13.0.95.3 Comment:

the min operator behavior depends on the nature of the operand

13.0.95.4 Special cases:

- if it is a list of points: min returns the minimum of all points as a point (i.e. the point with the smallest coordinate on the x-axis, in case of equality the point with the smallest coordinate on the y-axis is chosen. If all the points are equal, the first one is returned.)

- if it is a population of a list of other types: min transforms all elements into integer and returns the minimum of them

- if it is a map, min returns the minimum among the list of all elements value

- if it is a file, min returns the minimum of the content of the file (that is also a container)

- if it is a graph, min returns the minimum of the list of the elements of the graph (that can be the list of edges or vertexes depending on the graph)

- if it is a matrix of int, float or object, min returns the minimum of all the numerical elements (thus all elements for integer and float matrices)

- if it is a matrix of geometry, min returns the minimum of the list of the geometries

- if it is a matrix of another type, min returns the minimum of the elements transformed into float

- if it is a list of int or float: min returns the minimum of all the elements

```
unknown var0 <- min ([100, 23.2, 34.5]); // var0 equals 23.2
```

13.0.95.5 See also:

max,

13.0.96 min_of

13.0.96.1 Possible use:

- `container` **min_of** `any expression` —> `unknown`
- **min_of** (`container` , `any expression`) —> `unknown`

13.0.96.2 Result:

the minimum value of the right-hand expression evaluated on each of the elements of the left-hand operand

13.0.96.3 Comment:

in the right-hand operand, the keyword each can be used to represent, in turn, each of the right-hand operand elements.

13.0.96.4 Special cases:

- if the left-hand operand is nil or empty, min_of throws an error

- if the left-operand is a map, the keyword each will contain each value

```
unknown var4 <- [1::2, 3::4, 5::6] min_of (each + 3); // var4 equals 5
```

13.0.96.5 Examples:

```
unknown var0 <- [1,2,4,3,5,7,6,8] min_of (each * 100 ); // var0 equals 100graph g2 <- as_edge_graph([{1
unknown var2 <- g2 min_of (length(g2 out_edges_of each) ); // var2 equals 0
unknown var3 <- (list(node) min_of (round(node(each).location.x)); // var3 equals 4
```

13.0.96.6   See also:

max_of,

13.0.97   minus_days

13.0.97.1   Possible use:

- date **minus_days** int —> date
- **minus_days** (date , int) —> date

13.0.97.2   Result:

Subtract a given number of days from a date

13.0.97.3   Examples:

```
date var0 <- date('2000-01-01') minus_days 20; // var0 equals date('1999-12-12')
```

13.0.98   minus_hours

13.0.98.1   Possible use:

- date **minus_hours** int —> date
- **minus_hours** (date , int) —> date

13.0.98.2   Result:

Remove a given number of hours from a date

13.0.98.3   Examples:

```
// equivalent to date1 - 15 #h
date var1 <- date('2000-01-01') minus_hours 15 ; // var1 equals date('1999-12-31 09:00:00')
```

13.0.99   minus_minutes

13.0.99.1   Possible use:

- date **minus_minutes** int —> date
- **minus_minutes** (date , int) —> date

13.0.99.2 Result:

Subtract a given number of minutes from a date

13.0.99.3 Examples:

```
// date('2000-01-01') to date1 - 5#mn
date var1 <- date('2000-01-01') minus_minutes 5 ; // var1 equals date('1999-12-31 23:55:00')
```

13.0.100 minus_months

13.0.100.1 Possible use:

- date **minus_months** int —> date
- **minus_months** (date , int) —> date

13.0.100.2 Result:

Subtract a given number of months from a date

13.0.100.3 Examples:

```
date var0 <- date('2000-01-01') minus_months 5; // var0 equals date('1999-08-01')
```

13.0.101 minus_ms

13.0.101.1 Possible use:

- date **minus_ms** int —> date
- **minus_ms** (date , int) —> date

13.0.101.2 Result:

Remove a given number of milliseconds from a date

13.0.101.3 Examples:

```
// equivalent to date1 - 15 #ms
date var1 <- date('2000-01-01') minus_ms 1000 ; // var1 equals date('1999-12-31 23:59:59')
```

13.0.102 `minus_seconds`

Same signification as -

13.0.103 `minus_weeks`

13.0.103.1 Possible use:

- date **minus_weeks** int —> date
- **minus_weeks** (date , int) —> date

13.0.103.2 Result:

Subtract a given number of weeks from a date

13.0.103.3 Examples:

```
date var0 <- date('2000-01-01') minus_weeks 15; // var0 equals date('1999-09-18')
```

13.0.104 `minus_years`

13.0.104.1 Possible use:

- date **minus_years** int —> date
- **minus_years** (date , int) —> date

13.0.104.2 Result:

Subtract a given number of year from a date

13.0.104.3 Examples:

```
date var0 <- date('2000-01-01') minus_years 3; // var0 equals date('1997-01-01')
```

13.0.105 `mod`

13.0.105.1 Possible use:

- int **mod** int —> int
- **mod** (int , int) —> int

13.0.105.2 Result:

Returns the remainder of the integer division of the left-hand operand by the right-hand operand.

13.0.105.3 Special cases:

- if operands are float, they are truncated

- if the right-hand operand is equal to zero, raises an exception.

13.0.105.4 Examples:

```
int var0 <- 40 mod 3; // var0 equals 1
```

13.0.105.5 See also:

div,

13.0.106 moment

13.0.106.1 Possible use:

- **moment** (container, int, float) —> float

13.0.106.2 Result:

Returns the moment of k-th order with constant c of a data sequence

---

13.0.107 months_between

13.0.107.1 Possible use:

- date **months_between** date —> int
- **months_between** (date , date) —> int

13.0.107.2 Result:

Provide the exact number of months between two dates. This number can be positive or negative (if the second operand is smaller than the first one)

13.0.107.3 Examples:

```
int var0 <- months_between(date('2000-01-01'), date('2000-02-01')); // var0 equals 1
```

13.0.108 moran

13.0.108.1 Possible use:

- `list<float>` **moran** `matrix<float>` —> `float`
- **moran** (`list<float>` , `matrix<float>`) —> `float`

13.0.108.2 Special cases:

- return the Moran Index of the given list of interest points (list of floats) and the weight matrix (matrix of float)

```
float var0 <- moran([1.0, 0.5, 2.0], weight_matrix); // var0 equals the Moran index computed
```

13.0.109 mul

13.0.109.1 Possible use:

- **mul** (container) —> `unknown`

13.0.109.2 Result:

the product of all the elements of the operand

13.0.109.3 Comment:

the mul operator behavior depends on the nature of the operand

13.0.109.4 Special cases:

- if it is a list of points: mul returns the product of all points as a point (each coordinate is the product of the corresponding coordinate of each element)

- if it is a list of other types: mul transforms all elements into integer and multiplies them

- if it is a map, mul returns the product of the value of all elements

- if it is a file, mul returns the product of the content of the file (that is also a container)

- if it is a graph, mul returns the product of the list of the elements of the graph (that can be the list of edges or vertexes depending on the graph)

- if it is a matrix of int, float or object, mul returns the product of all the numerical elements (thus all elements for integer and float matrices)

- if it is a matrix of geometry, mul returns the product of the list of the geometries

- if it is a matrix of other types: mul transforms all elements into float and multiplies them

- if it is a list of int or float: mul returns the product of all the elements

```
unknown var0 <- mul ([100, 23.2, 34.5]); // var0 equals 80040.0
```

13.0.109.5   See also:

sum,

Chapter 14

Operators (N to R)

14.0.1 nb_cycles

14.0.1.1 Possible use:

- **nb_cycles** (graph) —> int

14.0.1.2 Result:

returns the maximum number of independent cycles in a graph. This number (u) is estimated through the number of nodes (v), links (e) and of sub-graphs (p): u = e - v + p.

14.0.1.3 Examples:

```
graph graphEpidemio <- graph([]);
int var1 <- nb_cycles(graphEpidemio); // var1 equals the number of cycles in the graph
```

14.0.1.4 See also:

alpha_index, beta_index, gamma_index, connectivity_index,

14.0.2 neighbors_at

14.0.2.1 Possible use:

- geometry **neighbors_at** float —> list
- **neighbors_at** (geometry , float) —> list

14.0.2.2   Result:

a list, containing all the agents of the same species than the left argument (if it is an agent) located at a
distance inferior or equal to the right-hand operand to the left-hand operand (geometry, agent, point).

14.0.2.3   Comment:

The topology used to compute the neighborhood is the one of the left-operand if this one is an agent;
otherwise the one of the agent applying the operator.

14.0.2.4   Examples:

```
list var0 <- (self neighbors_at (10)); // var0 equals all the agents located at a distance lower or equa
```

14.0.2.5   See also:

neighbors_of, closest_to, overlapping, agents_overlapping, agents_inside, agent_closest_to, at_distance,

---

14.0.3   `neighbors_of`

14.0.3.1   Possible use:

- graph **neighbors_of** unknown —> list
- **neighbors_of** (graph , unknown) —> list
- topology **neighbors_of** agent —> list
- **neighbors_of** (topology , agent) —> list
- **neighbors_of** (topology, geometry, float) —> list

14.0.3.2   Result:

a list, containing all the agents of the same species than the argument (if it is an agent) located at a distance
inferior or equal to 1 to the right-hand operand agent considering the left-hand operand topology.

14.0.3.3   Special cases:

- a list, containing all the agents of the same species than the left argument (if it is an agent) located at
  a distance inferior or equal to the third argument to the second argument (agent, geometry or point)
  considering the first operand topology.

```
list var3 <- neighbors_of (topology(self), self,10); // var3 equals all the agents located at a distance
```

14.0.3.4 Examples:

```
list var0 <- graphEpidemio neighbors_of (node(3)); // var0 equals [node0,node2]
list var1 <- graphFromMap neighbors_of node({12,45}); // var1 equals [{1.0,5.0},{34.0,56.0}]
list var2 <- topology(self) neighbors_of self; // var2 equals returns all the agents located at a dist
```

14.0.3.5 See also:

predecessors_of, successors_of, neighbors_at, closest_to, overlapping, agents_overlapping, agents_inside, agent_closest_to,

---

14.0.4 `new_emotion`

14.0.4.1 Possible use:

- **new_emotion** (string) —> emotion
- string **new_emotion** agent —> emotion
- **new_emotion** (string , agent) —> emotion
- string **new_emotion** predicate —> emotion
- **new_emotion** (string , predicate) —> emotion
- string **new_emotion** float —> emotion
- **new_emotion** (string , float) —> emotion
- **new_emotion** (string, predicate, agent) —> emotion
- **new_emotion** (string, float, float) —> emotion
- **new_emotion** (string, float, agent) —> emotion
- **new_emotion** (string, float, predicate) —> emotion
- **new_emotion** (string, float, predicate, agent) —> emotion
- **new_emotion** (string, float, float, agent) —> emotion
- **new_emotion** (string, float, predicate, float) —> emotion
- **new_emotion** (string, float, predicate, float, agent) —> emotion

14.0.4.2 Result:

a new emotion with the given properties (name) a new emotion with the given properties (name) a new emotion with the given properties (name) a new emotion with the given properties (name,about) a new emotion with the given properties (name) a new emotion with the given properties (name,intensity,decay) a new emotion with the given properties (name) a new emotion with the given properties (name) a new emotion with the given properties (name) a new emotion with the given properties (name, intensity) a new emotion with the given properties (name) a new emotion with the given properties (name,intensity,about)

14.0.4.3 Examples:

```
emotion("joy",12.3,eatFood,4) emotion("joy",12.3,eatFood,4) emotion("joy",12.3,eatFood,4) emotion("joy"
```

14.0.5 `new_folder`

14.0.5.1 Possible use:

- **new_folder** (string) —> file

14.0.5.2 Result:

opens an existing repository or create a new folder if it does not exist.

14.0.5.3 Special cases:

- If the specified string does not refer to an existing repository, the repository is created.

- If the string refers to an existing file, an exception is risen.

14.0.5.4 Examples:

```
file dirNewT <- new_folder("incl/");    // dirNewT represents the repository "../incl/"
```

14.0.5.5 See also:

folder, file,

14.0.6 `new_mental_state`

14.0.6.1 Possible use:

- **new_mental_state** (string) —> mental_state
- string **new_mental_state** predicate —> mental_state
- **new_mental_state** (string , predicate) —> mental_state
- string **new_mental_state** mental_state —> mental_state
- **new_mental_state** (string , mental_state) —> mental_state
- string **new_mental_state** emotion —> mental_state
- **new_mental_state** (string , emotion) —> mental_state
- **new_mental_state** (string, emotion, int) —> mental_state
- **new_mental_state** (string, predicate, agent) —> mental_state
- **new_mental_state** (string, predicate, int) —> mental_state
- **new_mental_state** (string, emotion, float) —> mental_state
- **new_mental_state** (string, predicate, float) —> mental_state
- **new_mental_state** (string, mental_state, float) —> mental_state
- **new_mental_state** (string, mental_state, int) —> mental_state
- **new_mental_state** (string, emotion, agent) —> mental_state
- **new_mental_state** (string, mental_state, agent) —> mental_state
- **new_mental_state** (string, mental_state, float, agent) —> mental_state
- **new_mental_state** (string, emotion, float, agent) —> mental_state
- **new_mental_state** (string, predicate, float, agent) —> mental_state
- **new_mental_state** (string, predicate, int, agent) —> mental_state
- **new_mental_state** (string, mental_state, float, int) —> mental_state

- **new_mental_state** (string, emotion, float, int) —> mental_state
- **new_mental_state** (string, predicate, float, int) —> mental_state
- **new_mental_state** (string, emotion, int, agent) —> mental_state
- **new_mental_state** (string, mental_state, int, agent) —> mental_state
- **new_mental_state** (string, mental_state, float, int, agent) —> mental_state
- **new_mental_state** (string, predicate, float, int, agent) —> mental_state
- **new_mental_state** (string, emotion, float, int, agent) —> mental_state

14.0.6.2 Result:

a new mental state a new mental state

14.0.6.3 Examples:

new_mental-state(belief) new_mental-state(belief) new_mental-state(belief) new_mental-state(belief) new_

14.0.7 `new_predicate`

14.0.7.1 Possible use:

- **new_predicate** (string) —> predicate
- string **new_predicate** int —> predicate
- **new_predicate** (string , int) —> predicate
- string **new_predicate** agent —> predicate
- **new_predicate** (string , agent) —> predicate
- string **new_predicate** map —> predicate
- **new_predicate** (string , map) —> predicate
- string **new_predicate** bool —> predicate
- **new_predicate** (string , bool) —> predicate
- **new_predicate** (string, map, int) —> predicate
- **new_predicate** (string, map, bool) —> predicate
- **new_predicate** (string, map, agent) —> predicate
- **new_predicate** (string, map, bool, agent) —> predicate
- **new_predicate** (string, map, int, bool) —> predicate
- **new_predicate** (string, map, int, agent) —> predicate
- **new_predicate** (string, map, int, bool, agent) —> predicate

14.0.7.2 Result:

a new predicate with the given properties (name, values, is_true, agentCause) a new predicate with the given properties (name, values, lifetime) a new predicate with the given properties (name) a new predicate with the given properties (name, values, lifetime, is_true) a new predicate with the given is_true (name, lifetime) a new predicate with the given properties (name, values, lifetime, is_true, agentCause) a new predicate with the given properties (name, values, is_true) a new predicate with the given properties (name, values, agentCause) a new predicate with the given properties (name, values, lifetime) a new predicate with the given

properties (name, values) a new predicate with the given properties (name, values, lifetime, agentCause) a new predicate with the given is_true (name, is_true)

14.0.7.3 Examples:

predicate("people to meet", ["time"::10], true, agentA) predicate("people to meet", ["time"::10], true)

14.0.8 `new_social_link`

14.0.8.1 Possible use:

- **new_social_link** (agent) —> msi.gaml.architecture.simplebdi.SocialLink
- **new_social_link** (agent, float, float, float, float) —> msi.gaml.architecture.simplebdi.SocialLink

14.0.8.2 Result:

a new social link a new social link

14.0.8.3 Examples:

new_social_link(agentA) new_social_link(agentA,0.0,-0.1,0.2,0.1)

14.0.9 `node`

14.0.9.1 Possible use:

- **node** (unknown) —> unknown
- unknown **node** float —> unknown
- **node** (unknown , float) —> unknown

14.0.10 `nodes`

14.0.10.1 Possible use:

- **nodes** (container) —> container

14.0.11 `norm`

14.0.11.1 Possible use:

- **norm** (point) —> float

14.0.11.2 Result:

the norm of the vector with the coordinates of the point operand.

14.0.11.3 Examples:

```
float var0 <- norm({3,4}); // var0 equals 5.0
```

14.0.12 Norm

14.0.12.1 Possible use:

- **Norm** (any) —> Norm

14.0.12.2 Result:

Casts the operand into the type Norm

14.0.13 normal_area

14.0.13.1 Possible use:

- **normal_area** (float, float, float) —> float

14.0.13.2 Result:

Returns the area to the left of x in the normal distribution with the given mean and standard deviation.

14.0.14 normal_density

14.0.14.1 Possible use:

- **normal_density** (float, float, float) —> float

14.0.14.2 Result:

Returns the probability of x in the normal distribution with the given mean and standard deviation.

14.0.15 `normal_inverse`

14.0.15.1 Possible use:

- **`normal_inverse`** (float, float, float) —> float

14.0.15.2 Result:

Returns the x in the normal distribution with the given mean and standard deviation, to the left of which lies the given area. normal.Inverse returns the value in terms of standard deviations from the mean, so we need to adjust it for the given mean and standard deviation.

14.0.16 `not`

Same signification as !

14.0.17 `obj_file`

14.0.17.1 Possible use:

- **`obj_file`** (string) —> file

14.0.17.2 Result:

Constructs a file of type obj. Allowed extensions are limited to obj, OBJ

14.0.18 `of`

Same signification as .

14.0.19 `of_generic_species`

14.0.19.1 Possible use:

- container **`of_generic_species`** species —> list
- **`of_generic_species`** (container , species) —> list

14.0.19.2 Result:

a list, containing the agents of the left-hand operand whose species is that denoted by the right-hand operand and whose species extends the right-hand operand species

14.0.19.3 Examples:

```
// species test {} // species sous_test parent: test {}
list var2 <- [sous_test(0),sous_test(1),test(2),test(3)] of_generic_species test; // var2 equals [sous_
list var3 <- [sous_test(0),sous_test(1),test(2),test(3)] of_generic_species sous_test; // var3 equals [s
list var4 <- [sous_test(0),sous_test(1),test(2),test(3)] of_species test; // var4 equals [test2,test3]
list var5 <- [sous_test(0),sous_test(1),test(2),test(3)] of_species sous_test; // var5 equals [sous_test
```

14.0.19.4 See also:

of_species,

14.0.20 of_species

14.0.20.1 Possible use:

- container **of_species** species —> list
- **of_species** (container , species) —> list

14.0.20.2 Result:

a list, containing the agents of the left-hand operand whose species is the one denoted by the right-hand operand.The expression agents of_species (species self) is equivalent to agents where (species each = species self); however, the advantage of using the first syntax is that the resulting list is correctly typed with the right species, whereas, in the second syntax, the parser cannot determine the species of the agents within the list (resulting in the need to cast it explicitly if it is to be used in an ask statement, for instance).

14.0.20.3 Special cases:

- if the right operand is nil, of_species returns the right operand

14.0.20.4 Examples:

```
list var0 <- (self neighbors_at 10) of_species (species (self)); // var0 equals all the neighboring age
list var1 <- [test(0),test(1),node(1),node(2)] of_species test; // var1 equals [test0,test1]
```

14.0.20.5 See also:

of_generic_species,

14.0.21 one_of

14.0.21.1 Possible use:

- **one_of** (container<KeyType,ValueType>) —> ValueType

14.0.21.2 Result:

one of the values stored in this container at a random key

14.0.21.3 Comment:

the one_of operator behavior depends on the nature of the operand

14.0.21.4 Special cases:

- if it is a graph, one_of returns one of the lists of edges

- if it is a file, one_of returns one of the elements of the content of the file (that is also a container)

- if the operand is empty, one_of returns nil

- if it is a list or a matrix, one_of returns one of the values of the list or of the matrix

```
int
i <- any ([1,2,3]); //i equals 1, 2 or 3string sMat <- one_of(matrix([["c11","c12","c13"],["c21","c22",
```

- if it is a map, one_of returns one the value of a random pair of the map

```
int im <- one_of ([2::3, 4::5, 6::7]);  // im equals 3, 5 or 7
bool var6 <- [2::3, 4::5, 6::7].values contains im; // var6 equals true
```

- if it is a population, one_of returns one of the agents of the population

```
bug b <- one_of(bug);    // Given a previously defined species bug, b is one of the created bugs, e.g. bu
```

14.0.21.5 See also:

contains,

14.0.22 open_simplex_generator

14.0.22.1 Possible use:

- **open_simplex_generator** (float, float, float) —> float

14.0.22.2 Result:

take a x, y and a bias parameters and gives a value

14.0.22.3 Examples:

```
float var0 <- open_simplex_generator(2,3,253); // var0 equals 10.2
```

14.0.23 or

14.0.23.1 Possible use:

- `bool` **or** `any expression` —> `bool`
- **or** (`bool` , `any expression`) —> `bool`

14.0.23.2 Result:

a bool value, equal to the logical or between the left-hand operand and the right-hand operand.

14.0.23.3 Comment:

both operands are always casted to bool before applying the operator. Thus, an expression like 1 or 0 is accepted and returns true.

14.0.23.4 See also:

bool, and, !,

14.0.24 or

14.0.24.1 Possible use:

- `predicate` **or** `predicate` —> `predicate`
- **or** (`predicate` , `predicate`) —> `predicate`

14.0.24.2 Result:

create a new predicate from two others by including them as subintentions. It's an exclusive "or"

14.0.24.3 Examples:

`predicate1 or predicate2`

14.0.25 osm_file

14.0.25.1 Possible use:

- `string` **osm_file** `map<string,list>` —> `file`
- **osm_file** (`string` , `map<string,list>`) —> `file`
- **osm_file** (`string`, `map<string,list>`, `int`) —> `file`

14.0.25.2 Result:

opens a file that a is a kind of OSM file with some filtering, forcing the initial CRS to be the one indicated by the second int parameter (see http://spatialreference.org/ref/epsg/). If this int parameter is equal to 0, the data is considered as already projected. opens a file that a is a kind of OSM file with some filtering.

14.0.25.3 Comment:

The file should have a OSM file extension, cf. file type definition for supported file extensions.The file should have a OSM file extension, cf. file type definition for supported file extensions.

14.0.25.4 Special cases:

- If the specified string does not refer to an existing OSM file, an exception is risen.

- If the specified string does not refer to an existing OSM file, an exception is risen.

14.0.25.5 Examples:

```
file myOSMfile2 <- osm_file("../includes/rouen.osm",["highway"::["primary","motorway"]], 0); file myOSM
```

14.0.25.6 See also:

file,

14.0.26 out_degree_of

14.0.26.1 Possible use:

- graph **out_degree_of** unknown —> int
- **out_degree_of** (graph , unknown) —> int

14.0.26.2 Result:

returns the out degree of a vertex (right-hand operand) in the graph given as left-hand operand.

14.0.26.3 Examples:

```
int var1 <- graphFromMap out_degree_of (node(3)); // var1 equals 4
```

14.0.26.4 See also:

in_degree_of, degree_of,

14.0.27 `out_edges_of`

14.0.27.1 Possible use:

- graph **out_edges_of** unknown —> list
- **out_edges_of** (graph , unknown) —> list

14.0.27.2 Result:

returns the list of the out-edges of a vertex (right-hand operand) in the graph given as left-hand operand.

14.0.27.3 Examples:

```
list var1 <- graphFromMap out_edges_of (node(3)); // var1 equals 3
```

14.0.27.4 See also:

in_edges_of,

14.0.28 `overlapping`

14.0.28.1 Possible use:

- container<agent> **overlapping** geometry —> list<geometry>
- **overlapping** (container<agent> , geometry) —> list<geometry>

14.0.28.2 Result:

A list of agents or geometries among the left-operand list, species or meta-population (addition of species), overlapping the operand (casted as a geometry).

14.0.28.3 Examples:

```
list<geometry> var0 <- [ag1, ag2, ag3] overlapping(self); // var0 equals return the agents among ag1, ag
```

14.0.28.4 See also:

neighbors_at, neighbors_of, agent_closest_to, agents_inside, closest_to, inside, agents_overlapping,

---

14.0.29 overlaps

14.0.29.1 Possible use:

- geometry **overlaps** geometry —> bool
- **overlaps** (geometry , geometry) —> bool

14.0.29.2 Result:

A boolean, equal to true if the left-geometry (or agent/point) overlaps the right-geometry (or agent/point).

14.0.29.3 Special cases:

- if one of the operand is null, returns false.

- if one operand is a point, returns true if the point is included in the geometry

14.0.29.4 Examples:

```
bool var0 <- polyline([{10,10},{20,20}]) overlaps polyline([{15,15},{25,25}]); // var0 equals true
bool var1 <- polygon([{10,10},{10,20},{20,20},{20,10}]) overlaps polygon([{15,15},{15,25},{25,25},{25,1!
bool var2 <- polygon([{10,10},{10,20},{20,20},{20,10}]) overlaps {25,25}; // var2 equals false
bool var3 <- polygon([{10,10},{10,20},{20,20},{20,10}]) overlaps polygon([{35,35},{35,45},{45,45},{45,3!
bool var4 <- polygon([{10,10},{10,20},{20,20},{20,10}]) overlaps polyline([{10,10},{20,20}]); // var4 eo
bool var5 <- polygon([{10,10},{10,20},{20,20},{20,10}]) overlaps {15,15}; // var5 equals true
bool var6 <- polygon([{10,10},{10,20},{20,20},{20,10}]) overlaps polygon([{0,0},{0,30},{30,30}, {30,0}]
bool var7 <- polygon([{10,10},{10,20},{20,20},{20,10}]) overlaps polygon([{15,15},{15,25},{25,25},{25,1!
bool var8 <- polygon([{10,10},{10,20},{20,20},{20,10}]) overlaps polygon([{10,20},{20,20},{20,30},{10,30
```

14.0.29.5 See also:

disjoint_from, crosses, intersects, partially_overlaps, touches,

---

14.0.30 pair

14.0.30.1 Possible use:

- **pair** (any) —> pair

14.0.30.2 Result:

Casts the operand into the type pair

14.0.31 `partially_overlaps`

14.0.31.1 Possible use:

- geometry **partially_overlaps** geometry —> bool
- **partially_overlaps** (geometry , geometry) —> bool

14.0.31.2 Result:

A boolean, equal to true if the left-geometry (or agent/point) partially overlaps the right-geometry (or agent/point).

14.0.31.3 Comment:

if one geometry operand fully covers the other geometry operand, returns false (contrarily to the overlaps operator).

14.0.31.4 Special cases:

- if one of the operand is null, returns false.

14.0.31.5 Examples:

```
bool var0 <- polyline([{10,10},{20,20}]) partially_overlaps polyline([{15,15},{25,25}]); // var0 equals
bool var1 <- polygon([{10,10},{10,20},{20,20},{20,10}]) partially_overlaps polygon([{15,15},{15,25},{25
bool var2 <- polygon([{10,10},{10,20},{20,20},{20,10}]) partially_overlaps {25,25}; // var2 equals false
bool var3 <- polygon([{10,10},{10,20},{20,20},{20,10}]) partially_overlaps polygon([{35,35},{35,45},{45
bool var4 <- polygon([{10,10},{10,20},{20,20},{20,10}]) partially_overlaps polyline([{10,10},{20,20}]);
bool var5 <- polygon([{10,10},{10,20},{20,20},{20,10}]) partially_overlaps {15,15}; // var5 equals false
bool var6 <- polygon([{10,10},{10,20},{20,20},{20,10}]) partially_overlaps polygon([{0,0},{0,30},{30,30}
bool var7 <- polygon([{10,10},{10,20},{20,20},{20,10}]) partially_overlaps polygon([{15,15},{15,25},{25
bool var8 <- polygon([{10,10},{10,20},{20,20},{20,10}]) partially_overlaps polygon([{10,20},{20,20},{20
```

14.0.31.6 See also:

disjoint_from, crosses, overlaps, intersects, touches,

14.0.32 `path`

14.0.32.1 Possible use:

- **path** (any) —> path

14.0.32.2   Result:

Casts the operand into the type path

14.0.33   `path_between`

14.0.33.1   Possible use:

- topology **path_between** container<geometry> —> path
- **path_between** (topology , container<geometry>) —> path
- msi.gama.util.GamaMap<msi.gama.metamodel.agent.IAgent,java.lang.Object> **path_between** container<geometry> —> path
- **path_between** (msi.gama.util.GamaMap<msi.gama.metamodel.agent.IAgent,java.lang.Object> , container<geometry>) —> path
- list<agent> **path_between** container<geometry> —> path
- **path_between** (list<agent> , container<geometry>) —> path
- **path_between** (topology, geometry, geometry) —> path
- **path_between** (list<agent>, geometry, geometry) —> path
- **path_between** (graph, geometry, geometry) —> path
- **path_between** (msi.gama.util.GamaMap<msi.gama.metamodel.agent.IAgent,java.lang.Object>, geometry, geometry) —> path

14.0.33.2   Result:

The shortest path between two objects according to set of cells The shortest path between a list of two objects in a graph The shortest path between two objects according to set of cells with corresponding weights The shortest path between several objects according to set of cells with corresponding weights The shortest path between several objects according to set of cells

14.0.33.3   Examples:

```
path var0 <- my_topology path_between (ag1, ag2); // var0 equals A path between ag1 and ag2
path var1 <- path_between (cell_grid where each.is_free, ag1, ag2); // var1 equals A path between ag1 an
path var2 <- my_topology path_between [ag1, ag2]; // var2 equals A path between ag1 and ag2
path var3 <- path_between (my_graph, ag1, ag2); // var3 equals A path between ag1 and ag2
path var4 <- path_between (cell_grid as_map (each::each.is_obstacle ? 9999.0 : 1.0), ag1, ag2); // var4
path var5 <- path_between (cell_grid as_map (each::each.is_obstacle ? 9999.0 : 1.0), [ag1, ag2, ag3]); /
path var6 <- path_between (cell_grid where each.is_free, [ag1, ag2, ag3]); // var6 equals A path between
```

14.0.33.4   See also:

towards, direction_to, distance_between, direction_between, path_to, distance_to,

---

14.0.34 `path_to`

14.0.34.1 Possible use:

- point **path_to** point —> path
- **path_to** (point , point) —> path
- geometry **path_to** geometry —> path
- **path_to** (geometry , geometry) —> path

14.0.34.2 Result:

A path between two geometries (geometries, agents or points) considering the topology of the agent applying the operator.

14.0.34.3 Examples:

path var0 <- ag1 path_to ag2; // var0 equals the path between ag1 and ag2 considering the topology of t

14.0.34.4 See also:

towards, direction_to, distance_between, direction_between, path_between, distance_to,

---

14.0.35 `paths_between`

14.0.35.1 Possible use:

- **paths_between** (graph, pair, int) —> msi.gama.util.IList<msi.gama.util.path.GamaSpatialPath>

14.0.35.2 Result:

The K shortest paths between a list of two objects in a graph

14.0.35.3 Examples:

msi.gama.util.IList<msi.gama.util.path.GamaSpatialPath> var0 <- paths_between(my_graph, ag1:: ag2, 2); /

14.0.36 `pbinom`

Same signification as binomial_sum

14.0.37 `pchisq`

Same signification as chi_square

14.0.38 `percent_absolute_deviation`

14.0.38.1 Possible use:

- `list<float>` **`percent_absolute_deviation`** `list<float>` —> float
- **`percent_absolute_deviation`** (list<float> , list<float>) —> float

14.0.38.2 Result:

percent absolute deviation indicator for 2 series of values: percent_absolute_deviation(list_vals_observe,list_vals_sim)

14.0.38.3 Examples:

`percent_absolute_deviation([200,300,150,150,200],[250,250,100,200,200])`

14.0.39 `percentile`

Same signification as quantile_inverse

14.0.40 `pgamma`

Same signification as gamma_distribution

14.0.41 `pgm_file`

14.0.41.1 Possible use:

- **`pgm_file`** (string) —> file

14.0.41.2 Result:

Constructs a file of type pgm. Allowed extensions are limited to pgm

---

14.0.42 `plan`

14.0.42.1 Possible use:

- container<geometry> **plan** float —> geometry
- **plan** (container<geometry> , float) —> geometry

14.0.42.2 Result:

A polyline geometry from the given list of points.

14.0.42.3 Special cases:

- if the operand is nil, returns the point geometry {0,0}

- if the operand is composed of a single point, returns a point geometry.

14.0.42.4 Examples:

```
geometry var0 <- polyplan([{0,0}, {0,10}, {10,10}, {10,0}],10); // var0 equals a polyline geometry comp
```

14.0.42.5 See also:

around, circle, cone, link, norm, point, polygone, rectangle, square, triangle,

---

14.0.43 `plus_days`

14.0.43.1 Possible use:

- date **plus_days** int —> date
- **plus_days** (date , int) —> date

14.0.43.2 Result:

Add a given number of days to a date

14.0.43.3 Examples:

```
date var0 <- date('2000-01-01') plus_days 12; // var0 equals date('2000-01-13')
```

14.0.44 `plus_hours`

14.0.44.1 Possible use:

- date **plus_hours** int —> date
- **plus_hours** (date , int) —> date

14.0.44.2 Result:

Add a given number of hours to a date

14.0.44.3 Examples:

```
// equivalent to date1 + 15 #h
date var1 <- date('2000-01-01') plus_hours 24; // var1 equals date('2000-01-02')
```

14.0.45 `plus_minutes`

14.0.45.1 Possible use:

- date **plus_minutes** int —> date
- **plus_minutes** (date , int) —> date

14.0.45.2 Result:

Add a given number of minutes to a date

14.0.45.3 Examples:

```
// equivalent to date1 + 5 #mn
date var1 <- date('2000-01-01') plus_minutes 5 ; // var1 equals date('2000-01-01 00:05:00')
```

14.0.46 `plus_months`

14.0.46.1 Possible use:

- date **plus_months** int —> date
- **plus_months** (date , int) —> date

14.0.46.2 Result:

Add a given number of months to a date

14.0.46.3 Examples:

```
date var0 <- date('2000-01-01') plus_months 5; // var0 equals date('2000-06-01')
```

14.0.47 plus_ms

14.0.47.1 Possible use:

- date **plus_ms** int —> date
- **plus_ms** (date , int) —> date

14.0.47.2 Result:

Add a given number of milliseconds to a date

14.0.47.3 Examples:

```
// equivalent to date('2000-01-01') + 15 #ms
date var1 <- date('2000-01-01') plus_ms 1000 ; // var1 equals date('2000-01-01 00:00:01')
```

14.0.48 plus_seconds

Same signification as +

14.0.49 plus_weeks

14.0.49.1 Possible use:

- date **plus_weeks** int —> date
- **plus_weeks** (date , int) —> date

14.0.49.2 Result:

Add a given number of weeks to a date

14.0.49.3 Examples:

```
date var0 <- date('2000-01-01') plus_weeks 15; // var0 equals date('2000-04-15')
```

14.0.50 `plus_years`

14.0.50.1 Possible use:

- date **plus_years** int —> date
- **plus_years** (date , int) —> date

14.0.50.2 Result:

Add a given number of years to a date

14.0.50.3 Examples:

```
date var0 <- date('2000-01-01') plus_years 15; // var0 equals date('2015-01-01')
```

14.0.51 `pnorm`

Same signification as normal_area

14.0.52 `point`

14.0.52.1 Possible use:

- **point** (any) —> point

14.0.52.2 Result:

Casts the operand into the type point

14.0.53 `points_along`

14.0.53.1 Possible use:

- geometry **points_along** list<float> —> list
- **points_along** (geometry , list<float>) —> list

14.0.53.2 Result:

A list of points along the operand-geometry given its location in terms of rate of distance from the starting points of the geometry.

14.0.53.3 Examples:

```
list var0 <-  line([{10,10},{80,80}]) points_along ([0.3, 0.5, 0.9]); // var0 equals the list of follow
```

14.0.53.4 See also:

closest_points_with, farthest_point_to, points_at, points_on,

––––––––––––––––––––––––––––––––––

14.0.54 `points_at`

14.0.54.1 Possible use:

- int **points_at** float —> list<point>
- **points_at** (int , float) —> list<point>

14.0.54.2 Result:

A list of left-operand number of points located at a the right-operand distance to the agent location.

14.0.54.3 Examples:

```
list<point> var0 <- 3 points_at(20.0); // var0 equals returns [pt1, pt2, pt3] loc
```

14.0.54.4 See also:

any_location_in, any_point_in, closest_points_with, farthest_point_to,

––––––––––––––––––––––––––––––––––

14.0.55 `points_on`

14.0.55.1 Possible use:

- geometry **points_on** float —> list
- **points_on** (geometry , float) —> list

14.0.55.2 Result:

A list of points of the operand-geometry distant from each other to the float right-operand .

14.0.55.3 Examples:

```
list var0 <-  square(5) points_on(2); // var0 equals a list of points belonging to the exterior ring of
```

14.0.55.4 See also:

closest_points_with, farthest_point_to, points_at,

14.0.56 `poisson`

14.0.56.1 Possible use:

- `poisson` (float) —> int

14.0.56.2 Result:

A value from a random variable following a Poisson distribution (with the positive expected number of occurence lambda as operand).

14.0.56.3 Comment:

The Poisson distribution is a discrete probability distribution that expresses the probability of a given number of events occurring in a fixed interval of time and/or space if these events occur with a known average rate and independently of the time since the last event, cf. Poisson distribution on Wikipedia.

14.0.56.4 Examples:

```
int var0 <- poisson(3.5); // var0 equals a random positive integer
```

14.0.56.5 See also:

binomial, gauss,

14.0.57 `polygon`

14.0.57.1 Possible use:

- `polygon` (container<agent>) —> geometry

14.0.57.2 Result:

A polygon geometry from the given list of points.

14.0.57.3 Special cases:

- if the operand is nil, returns the point geometry {0,0}

- if the operand is composed of a single point, returns a point geometry

- if the operand is composed of 2 points, returns a polyline geometry.

14.0.57.4 Examples:

```
geometry var0 <- polygon([{0,0}, {0,10}, {10,10}, {10,0}]); // var0 equals a polygon geometry composed
```

14.0.57.5 See also:

around, circle, cone, line, link, norm, point, polyline, rectangle, square, triangle,

---

14.0.58 polyhedron

14.0.58.1 Possible use:

- container<geometry> **polyhedron** float —> geometry
- **polyhedron** (container<geometry> , float) —> geometry

14.0.58.2 Result:

A polyhedron geometry from the given list of points.

14.0.58.3 Special cases:

- if the operand is nil, returns the point geometry {0,0}

- if the operand is composed of a single point, returns a point geometry

- if the operand is composed of 2 points, returns a polyline geometry.

14.0.58.4 Examples:

```
geometry var0 <- polyhedron([{0,0}, {0,10}, {10,10}, {10,0}],10); // var0 equals a polygon geometry comp
```

14.0.58.5 See also:

around, circle, cone, line, link, norm, point, polyline, rectangle, square, triangle,

---

14.0.59 polyline

Same signification as line

14.0.60 polyplan

Same signification as plan

14.0.61 predecessors_of

14.0.61.1 Possible use:

- graph **predecessors_of** unknown —> list
- **predecessors_of** (graph , unknown) —> list

14.0.61.2 Result:

returns the list of predecessors (i.e. sources of in edges) of the given vertex (right-hand operand) in the given graph (left-hand operand)

14.0.61.3 Examples:

```
list var1 <- graphEpidemio predecessors_of ({1,5}); // var1 equals []
list var2 <- graphEpidemio predecessors_of node({34,56}); // var2 equals [{12;45}]
```

14.0.61.4 See also:

neighbors_of, successors_of,

14.0.62 predicate

14.0.62.1 Possible use:

- **predicate** (any) —> predicate

14.0.62.2 Result:

Casts the operand into the type predicate

14.0.63 `predict`

14.0.63.1 Possible use:

- `regression` **`predict`** `list<float>` —> `float`
- **`predict`** (`regression` , `list<float>`) —> `float`

14.0.63.2 Result:

returns the value predict by the regression parameters for a given instance. Usage: predict(regression, instance)

14.0.63.3 Examples:

```
predict(my_regression, [1,2,3])
```

14.0.64 `product`

Same signification as mul

14.0.65 `product_of`

14.0.65.1 Possible use:

- `container` **`product_of`** `any expression` —> `unknown`
- **`product_of`** (`container` , `any expression`) —> `unknown`

14.0.65.2 Result:

the product of the right-hand expression evaluated on each of the elements of the left-hand operand

14.0.65.3 Comment:

in the right-hand operand, the keyword each can be used to represent, in turn, each of the right-hand operand elements.

14.0.65.4 Special cases:

- if the left-operand is a map, the keyword each will contain each value

```
unknown var1 <- [1::2, 3::4, 5::6] product_of (each); // var1 equals 48
```

14.0.65.5   Examples:

```
unknown var0 <- [1,2] product_of (each * 10 ); // var0 equals 200
```

14.0.65.6   See also:

min_of, max_of, sum_of, mean_of,

14.0.66   `promethee_DM`

14.0.66.1   Possible use:

- msi.gama.util.IList<java.util.List> **promethee_DM** msi.gama.util.IList<java.util.Map<java.lang.String,
  —> int
- **promethee_DM** (msi.gama.util.IList<java.util.List> , msi.gama.util.IList<java.util.Map<java.lang.Strin
  —> int

14.0.66.2   Result:

The index of the best candidate according to the Promethee II method. This method is based on a compari-
son per pair of possible candidates along each criterion: all candidates are compared to each other by pair and
ranked. More information about this method can be found in [http://www.sciencedirect.com/science?_ob=
ArticleURL&_udi=B6VCT-4VF56TV-1&_user=10&_coverDate=01%2F01%2F2010&_rdoc=1&_fmt=
high&_orig=search&_sort=d&_docanchor=&view=c&_searchStrId=1389284642&_rerunOrigin=google&_acct=C000050
Behzadian, M., Kazemzadeh, R., Albadvi, A., M., A.: PROMETHEE: A comprehensive literature review
on methodologies and applications. European Journal of Operational Research(2009)]. The first operand is
the list of candidates (a candidate is a list of criterion values); the second operand the list of criterion: A
criterion is a map that contains fours elements: a name, a weight, a preference value (p) and an indifference
value (q). The preference value represents the threshold from which the difference between two criterion
values allows to prefer one vector of values over another. The indifference value represents the threshold
from which the difference between two criterion values is considered significant.

14.0.66.3   Special cases:

- returns -1 is the list of candidates is nil or empty

14.0.66.4   Examples:

```
int var0 <- promethee_DM([[1.0, 7.0],[4.0,2.0],[3.0, 3.0]], [["name"::"utility", "weight" :: 2.0,"p"::0
```

14.0.66.5   See also:

weighted_means_DM, electre_DM, evidence_theory_DM,

14.0.67 `property_file`

14.0.67.1 Possible use:

- `property_file` (string) —> file

14.0.67.2 Result:

Constructs a file of type property. Allowed extensions are limited to properties

---

14.0.68 `pValue_for_fStat`

14.0.68.1 Possible use:

- `pValue_for_fStat` (float, int, int) —> float

14.0.68.2 Result:

Returns the P value of F statistic fstat with numerator degrees of freedom dfn and denominator degress of freedom dfd. Uses the incomplete Beta function.

14.0.69 `pValue_for_tStat`

14.0.69.1 Possible use:

- float `pValue_for_tStat` int —> float
- `pValue_for_tStat` (float , int) —> float

14.0.69.2 Result:

Returns the P value of the T statistic tstat with df degrees of freedom. This is a two-tailed test so we just double the right tail which is given by studentT of -|tstat|.

14.0.70 `pyramid`

14.0.70.1 Possible use:

- `pyramid` (float) —> geometry

14.0.70.2 Result:

A square geometry which side size is given by the operand.

14.0.70.3 Comment:

the center of the pyramid is by default the location of the current agent in which has been called this operator.

14.0.70.4 Special cases:

- returns nil if the operand is nil.

14.0.70.5 Examples:

```
geometry var0 <- pyramid(5); // var0 equals a geometry as a square with side_size = 5.
```

14.0.70.6 See also:

around, circle, cone, line, link, norm, point, polygon, polyline, rectangle, square,

---

14.0.71 `quantile`

14.0.71.1 Possible use:

- container **quantile** float —> float
- **quantile** (container , float) —> float

14.0.71.2 Result:

Returns the phi-quantile; that is, an element elem for which holds that phi percent of data elements are less than elem. The quantile need not necessarily be contained in the data sequence, it can be a linear interpolation. Note that the container holding the values must be sorted first

---

14.0.72 `quantile_inverse`

14.0.72.1 Possible use:

- container **quantile_inverse** float —> float
- **quantile_inverse** (container , float) —> float

14.0.72.2 Result:

Returns how many percent of the elements contained in the receiver are <= element. Does linear interpolation if the element is not contained but lies in between two contained elements. Note that the container holding the values must be sorted first

---

14.0.73 R_correlation

Same signification as corR

14.0.74 R_file

14.0.74.1 Possible use:

- **R_file** (string) —> file

14.0.74.2 Result:

Constructs a file of type R. Allowed extensions are limited to r

---

14.0.75 R_mean

Same signification as meanR

14.0.76 range

14.0.76.1 Possible use:

- **range** (int) —> list
- int **range** int —> list
- **range** (int , int) —> list
- **range** (int, int, int) —> list

14.0.76.2 Result:

Allows to build a list of int representing all contiguous values from zero to the argument. The range can be increasing or decreasing. Passing 0 will return a singleton list with 0 Allows to build a list of int representing all contiguous values from the first to the second argument, using the step represented by the third argument. The range can be increasing or decreasing. Passing the same value for both will return a singleton list with this value. Passing a step of 0 will result in an exception. Attempting to build infinite ranges (e.g. end > start with a negative step) will similarly not be accepted and yield an exception Allows to build a list of int representing all contiguous values from the first to the second argument. The range can be increasing or decreasing. Passing the same value for both will return a singleton list with this value

---

14.0.77 rank_interpolated

14.0.77.1 Possible use:

- container **rank_interpolated** float —> float

- **rank_interpolated** (container , float) —> float

14.0.77.2 Result:

Returns the linearly interpolated number of elements in a list less or equal to a given element. The rank is the number of elements <= element. Ranks are of the form {0, 1, 2,..., sortedList.size()}. If no element is <= element, then the rank is zero. If the element lies in between two contained elements, then linear interpolation is used and a non integer value is returned. Note that the container holding the values must be sorted first

---

14.0.78 **read**

14.0.78.1 Possible use:

- **read** (string) —> unknown

14.0.78.2 Result:

Reads an attribute of the agent. The attribute's name is specified by the operand.

14.0.78.3 Examples:

```
unknown
agent_name <- read ('name'); //agent_name equals reads the 'name' variable of agent then assigns the re
```

14.0.79 **rectangle**

14.0.79.1 Possible use:

- **rectangle** (point) —> geometry
- float **rectangle** float —> geometry
- **rectangle** (float , float) —> geometry
- point **rectangle** point —> geometry
- **rectangle** (point , point) —> geometry

14.0.79.2 Result:

A rectangle geometry which side sizes are given by the operands.

14.0.79.3 Comment:

the center of the rectangle is by default the location of the current agent in which has been called this operator.the center of the rectangle is by default the location of the current agent in which has been called this operator.

14.0.79.4 Special cases:

- returns nil if the operand is nil.

- returns nil if the operand is nil.

- returns nil if the operand is nil.

14.0.79.5 Examples:

```
geometry var0 <- rectangle(10, 5); // var0 equals a geometry as a rectangle with width = 10 and height =
geometry var1 <- rectangle({2.0,6.0}, {6.0,20.0}); // var1 equals a geometry as a rectangle with {2.0,6
geometry var2 <- rectangle({10, 5}); // var2 equals a geometry as a rectangle with width = 10 and heigh
```

14.0.79.6 See also:

around, circle, cone, line, link, norm, point, polygon, polyline, square, triangle,

---

14.0.80 reduced_by

Same signification as -

14.0.81 regression

14.0.81.1 Possible use:

- **regression** (any) —> regression

14.0.81.2 Result:

Casts the operand into the type regression

14.0.82 remove_duplicates

Same signification as distinct

14.0.83 `remove_node_from`

14.0.83.1 Possible use:

- geometry **`remove_node_from`** graph —> graph
- **`remove_node_from`** (geometry , graph) —> graph

14.0.83.2 Result:

removes a node from a graph.

14.0.83.3 Comment:

all the edges containing this node are also removed.

14.0.83.4 Examples:

graph var0 <- node(0) remove_node_from graphEpidemio; // var0 equals the graph without node(0)

─────────────────────────────

14.0.84 `replace`

14.0.84.1 Possible use:

- **`replace`** (string, string, string) —> string

14.0.84.2 Result:

Returns the String resulting by replacing for the first operand all the sub-strings corresponding the second operand by the third operand

14.0.84.3 Examples:

string var0 <- replace('to be or not to be,that is the question','to', 'do'); // var0 equals 'do be or n

14.0.84.4 See also:

replace_regex,

─────────────────────────────

14.0.85 `replace_regex`

14.0.85.1 Possible use:

- **`replace_regex`** (string, string, string) —> string

14.0.85.2 Result:

Returns the String resulting by replacing for the first operand all the sub-strings corresponding to the regular expression given in the second operand by the third operand

14.0.85.3 Examples:

```
string var0 <- replace_regex("colour, color", "colou?r", "col"); // var0 equals 'col, col'
```

14.0.85.4 See also:

replace,

14.0.86 restoreSimulation

14.0.86.1 Possible use:

- **restoreSimulation** (string) —> int

14.0.86.2 Result:

restoreSimulation

14.0.87 restoreSimulationFromFile

14.0.87.1 Possible use:

- **restoreSimulationFromFile** (ummisco.gama.serializer.gaml.GamaSavedSimulationFile) —> int

14.0.87.2 Result:

restoreSimulationFromFile

14.0.88 reverse

14.0.88.1 Possible use:

- **reverse** (msi.gama.util.GamaMap<K,V>) —> container
- **reverse** (container<KeyType,ValueType>) —> container
- **reverse** (string) —> string

14.0.88.2 Result:

the operand elements in the reversed order in a copy of the operand.

14.0.88.3 Comment:

the reverse operator behavior depends on the nature of the operand

14.0.88.4 Special cases:

- if it is a file, reverse returns a copy of the file with a reversed content

- if it is a population, reverse returns a copy of the population with elements in the reversed order

- if it is a graph, reverse returns a copy of the graph (with all edges and vertexes), with all of the edges reversed

- if it is a list, reverse returns a copy of the operand list with elements in the reversed order

```
container var0 <- reverse ([10,12,14]); // var0 equals [14, 12, 10]
```

- if it is a map, reverse returns a copy of the operand map with each pair in the reversed order (i.e. all keys become values and values become keys)

```
map<int,string> var1 <- reverse (['k1'::44, 'k2'::32, 'k3'::12]); // var1 equals [44::'k1', 32::'k2', 1:
```

- if it is a matrix, reverse returns a new matrix containing the transpose of the operand.

```
container var2 <- reverse(matrix([["c11","c12","c13"],["c21","c22","c23"]])); // var2 equals matrix([["
```

- if it is a string, reverse returns a new string with characters in the reversed order

```
string var3 <- reverse ('abcd'); // var3 equals 'dcba'
```

14.0.89 rewire_n

14.0.89.1 Possible use:

- graph **rewire_n** int —> graph
- **rewire_n** (graph , int) —> graph

14.0.89.2 Result:

rewires the given count of edges.

14.0.89.3 Comment:

If there are too many edges, all the edges will be rewired.

14.0.89.4 Examples:

```
graph var1 <- graphEpidemio rewire_n 10; // var1 equals the graph with 3 edges rewired
```

14.0.90 `rgb`

14.0.90.1 Possible use:

- string **rgb** int —> rgb
- **rgb** (string , int) —> rgb
- rgb **rgb** int —> rgb
- **rgb** (rgb , int) —> rgb
- rgb **rgb** float —> rgb
- **rgb** (rgb , float) —> rgb
- **rgb** (int, int, int) —> rgb
- **rgb** (int, int, int, float) —> rgb
- **rgb** (int, int, int, int) —> rgb

14.0.90.2 Result:

Returns a color defined by red, green, blue components and an alpha blending value.

14.0.90.3 Special cases:

- It can be used with a name of color and alpha (between 0 and 255)

- It can be used with r=red, g=green, b=blue (each between 0 and 255), a=alpha (between 0.0 and 1.0)

- It can be used with r=red, g=green, b=blue (each between 0 and 255), a=alpha (between 0 and 255)

- It can be used with r=red, g=green, b=blue, each between 0 and 255

- It can be used with a color and an alpha between 0 and 255

- It can be used with a color and an alpha between 0 and 1

14.0.90.4 Examples:

```
rgb var0 <- rgb ("red"); // var0 equals rgb(255,0,0)
rgb var1 <- rgb (255,0,0,0.5); // var1 equals a light red color
rgb var2 <- rgb (255,0,0,125); // var2 equals a light red color
rgb var4 <- rgb (255,0,0); // var4 equals #red
rgb var5 <- rgb(rgb(255,0,0),125); // var5 equals a light red color
rgb var6 <- rgb(rgb(255,0,0),0.5); // var6 equals a light red color
```

14.0.90.5   See also:

hsb,

14.0.91   `rgb`

14.0.91.1   Possible use:

- **rgb** (any) —> rgb

14.0.91.2   Result:

Casts the operand into the type rgb

14.0.92   `rgb_to_xyz`

14.0.92.1   Possible use:

- **rgb_to_xyz** (file) —> list<point>

14.0.92.2   Result:

A list of point corresponding to RGB value of an image (r:x , g:y, b:z)

14.0.92.3   Examples:

```
list<point> var0 <- rgb_to_xyz(texture); // var0 equals a list of points
```

14.0.93   `rms`

14.0.93.1   Possible use:

- int **rms** float —> float
- **rms** (int , float) —> float

14.0.93.2   Result:

Returns the RMS (Root-Mean-Square) of a data sequence. The RMS of data sequence is the square-root of the mean of the squares of the elements in the data sequence. It is a measure of the average size of the elements of a data sequence.

14.0.94 rnd

14.0.94.1 Possible use:

- **rnd** (float) —> float
- **rnd** (int) —> int
- **rnd** (point) —> point
- point **rnd** point —> point
- **rnd** (point , point) —> point
- float **rnd** float —> float
- **rnd** (float , float) —> float
- int **rnd** int —> int
- **rnd** (int , int) —> int
- **rnd** (float, float, float) —> float
- **rnd** (point, point, float) —> point
- **rnd** (int, int, int) —> int

14.0.94.2 Result:

a random integer in the interval [0, operand]

14.0.94.3 Comment:

to obtain a probability between 0 and 1, use the expression (rnd n) / n, where n is used to indicate the precision

14.0.94.4 Special cases:

- if the operand is a float, returns an uniformly distributed float random number in [0.0, to]

- if the operand is a point, returns a point with three random float ordinates, each in the interval [0, ordinate of argument]

14.0.94.5 Examples:

```
float var0 <- rnd(3.4); // var0 equals a random float between 0.0 and 3.4
int var1 <- rnd (2); // var1 equals 0, 1 or 2
float var2 <- rnd (1000) / 1000; // var2 equals a float between 0 and 1 with a precision of 0.001
float var3 <- rnd (2.0, 4.0, 0.5); // var3 equals a float number between 2.0 and 4.0 every 0.5
point var4 <- rnd ({2.0, 4.0}, {2.0, 5.0, 10.0}); // var4 equals a point with x = 2.0, y between 2.0 and
float var5 <- rnd (2.0, 4.0); // var5 equals a float number between 2.0 and 4.0
point var6 <- rnd ({2.5,3, 0.0}); // var6 equals {x,y} with x in [0.0,2.0], y in [0.0,3.0], z = 0.0
int var7 <- rnd (2, 4); // var7 equals 2, 3 or 4
point var8 <- rnd ({2.0, 4.0}, {2.0, 5.0, 10.0}, 1); // var8 equals a point with x = 2.0, y equal to 2.0
int var9 <- rnd (2, 12, 4); // var9 equals 2, 6 or 10
```

14.0.94.6 See also:

flip,

14.0.95 `rnd_choice`

14.0.95.1 Possible use:

- **rnd_choice** (list) —> int

14.0.95.2 Result:

returns an index of the given list with a probability following the (normalized) distribution described in the
list (a form of lottery)

14.0.95.3 Examples:

```
int var0 <- rnd_choice([0.2,0.5,0.3]); // var0 equals 2/10 chances to return 0, 5/10 chances to return
```

14.0.95.4 See also:

rnd,

14.0.96 `rnd_color`

14.0.96.1 Possible use:

- **rnd_color** (int) —> rgb
- int **rnd_color** int —> rgb
- **rnd_color** (int , int) —> rgb

14.0.96.2 Result:

rgb color rgb color

14.0.96.3 Comment:

Return a random color equivalent to rgb(rnd(operand),rnd(operand),rnd(operand))Return a random color
equivalent to rgb(rnd(first_op, last_op),rnd(first_op, last_op),rnd(first_op, last_op))

14.0.96.4 Examples:

```
rgb var0 <- rnd_color(255); // var0 equals a random color, equivalent to rgb(rnd(255),rnd(255),rnd(255))
rgb var1 <- rnd_color(100, 200); // var1 equals a random color, equivalent to rgb(rnd(100, 200),rnd(100
```

14.0.96.5 See also:

rgb, hsb,

14.0.97 `rotated_by`

14.0.97.1 Possible use:

- geometry **rotated_by** float —> geometry
- **rotated_by** (geometry , float) —> geometry
- geometry **rotated_by** int —> geometry
- **rotated_by** (geometry , int) —> geometry
- **rotated_by** (geometry, float, point) —> geometry

14.0.97.2 Result:

A geometry resulting from the application of a rotation by the right-hand operand angle (degree) to the left-hand operand (geometry, agent, point) A geometry resulting from the application of a rotation by the right-hand operand angles (degree) along the three axis (x,y,z) to the left-hand operand (geometry, agent, point)

14.0.97.3 Comment:

the right-hand operand can be a float or a int

14.0.97.4 Examples:

```
geometry var0 <- self rotated_by 45; // var0 equals the geometry resulting from a 45 degrees rotation t
geometry var1 <- rotated_by(pyramid(10),45, {1,0,0}); // var1 equals the geometry resulting from a 45 de
```

transformed_by, translated_by,

14.0.98 `round`

14.0.98.1 Possible use:

- **round** (float) —> int
- **round** (int) —> int
- **round** (point) —> point

14.0.98.2 Result:

Returns the rounded value of the operand.

14.0.98.3 Special cases:

- if the operand is an int, round returns it

14.0.98.4 Examples:

```
int var0 <- round (0.51); // var0 equals 1
int var1 <- round (100.2); // var1 equals 100
int var2 <- round(-0.51); // var2 equals -1
point var3 <- {12345.78943,  12345.78943, 12345.78943} with_precision 2; // var3 equals {12345.79,12345
```

14.0.98.5 See also:

int, with_precision, round,

14.0.99 `row_at`

14.0.99.1 Possible use:

- matrix **row_at** int —> list
- **row_at** (matrix , int) —> list

14.0.99.2 Result:

returns the row at a num_line (right-hand operand)

14.0.99.3 Examples:

```
list var0 <- matrix([["el11","el12","el13"],["el21","el22","el23"],["el31","el32","el33"]]) row_at 2; //
```

14.0.99.4 See also:

column_at, columns_list,

14.0.100 `rows_list`

14.0.100.1 Possible use:

- **rows_list** (matrix) —> list<list>

14.0.100.2 Result:

returns a list of the rows of the matrix, with each row as a list of elements

14.0.100.3   Examples:

```
list<list> var0 <- rows_list(matrix([["el11","el12","el13"],["el21","el22","el23"],["el31","el32","el33
```

14.0.100.4   See also:

columns_list,

Chapter 15

Operators (S to Z)

15.0.1 `sample`

15.0.1.1 Possible use:

- **sample** (any expression) —> string
- string **sample** any expression —> string
- **sample** (string , any expression) —> string
- **sample** (list, int, bool) —> list
- **sample** (list, int, bool, list) —> list

15.0.1.2 Result:

takes a sample of the specified size from the elements of x using either with or without replacement with given weights takes a sample of the specified size from the elements of x using either with or without replacement

15.0.1.3 Examples:

```
list var0 <- sample([2,10,1],2,false,[0.1,0.7,0.2]); // var0 equals [10,2]
list var1 <- sample([2,10,1],2,false); // var1 equals [1,2]
```

15.0.2 `Sanction`

15.0.2.1 Possible use:

- **Sanction** (any) —> Sanction

15.0.2.2 Result:

Casts the operand into the type Sanction

15.0.3 saveAgent

15.0.3.1 Possible use:

- agent **saveAgent** string —> int
- **saveAgent** (agent , string) —> int

15.0.4 saved_simulation_file

15.0.4.1 Possible use:

- **saved_simulation_file** (string) —> file

15.0.4.2 Result:

Constructs a file of type saved_simulation. Allowed extensions are limited to gsim, gasim

---

15.0.5 saveSimulation

15.0.5.1 Possible use:

- **saveSimulation** (string) —> int

15.0.6 scaled_by

Same signification as *

15.0.7 scaled_to

15.0.7.1 Possible use:

- geometry **scaled_to** point —> geometry
- **scaled_to** (geometry , point) —> geometry

15.0.7.2 Result:

allows to restrict the size of a geometry so that it fits in the envelope {width, height, depth} defined by the second operand

15.0.7.3 Examples:

```
geometry var0 <- shape scaled_to {10,10}; // var0 equals a geometry corresponding to the geometry of th
```

15.0.8 `select`

Same signification as where

15.0.9 `serialize`

15.0.9.1 Possible use:

- **serialize** (unknown) —> string

15.0.9.2 Result:

It serializes any object, i.e. transform it into a string.

15.0.10 `serializeAgent`

15.0.10.1 Possible use:

- **serializeAgent** (agent) —> string

15.0.11 `set_about`

15.0.11.1 Possible use:

- emotion **set_about** predicate —> emotion
- **set_about** (emotion , predicate) —> emotion

15.0.11.2 Result:

change the about value of the given emotion

15.0.11.3 Examples:

```
emotion set_about predicate1
```

15.0.12 set_agent

15.0.12.1 Possible use:

- msi.gaml.architecture.simplebdi.SocialLink **set_agent** agent —> msi.gaml.architecture.simplebdi.Social
- **set_agent** (msi.gaml.architecture.simplebdi.SocialLink , agent) —> msi.gaml.architecture.simplebdi.Soc

15.0.12.2 Result:

change the agent value of the given social link

15.0.12.3 Examples:

```
social_link set_agent agentA
```

15.0.13 set_agent_cause

15.0.13.1 Possible use:

- predicate **set_agent_cause** agent —> predicate
- **set_agent_cause** (predicate , agent) —> predicate
- emotion **set_agent_cause** agent —> emotion
- **set_agent_cause** (emotion , agent) —> emotion

15.0.13.2 Result:

change the agentCause value of the given predicate change the agentCause value of the given emotion

15.0.13.3 Examples:

```
predicate set_agent_cause agentA emotion set_agent_cause agentA
```

15.0.14 set_decay

15.0.14.1 Possible use:

- emotion **set_decay** float —> emotion
- **set_decay** (emotion , float) —> emotion

15.0.14.2 Result:

change the decay value of the given emotion

15.0.14.3 Examples:

```
emotion set_decay 12
```

15.0.15 `set_dominance`

15.0.15.1 Possible use:

- `msi.gaml.architecture.simplebdi.SocialLink` **set_dominance** float —> msi.gaml.architecture.simplebdi.So
- **set_dominance** (msi.gaml.architecture.simplebdi.SocialLink , float) —> msi.gaml.architecture.simplebdi

15.0.15.2 Result:

change the dominance value of the given social link

15.0.15.3 Examples:

```
social_link set_dominance 0.4
```

15.0.16 `set_familiarity`

15.0.16.1 Possible use:

- `msi.gaml.architecture.simplebdi.SocialLink` **set_familiarity** float —> msi.gaml.architecture.simplebdi.
- **set_familiarity** (msi.gaml.architecture.simplebdi.SocialLink , float) —> msi.gaml.architecture.simpleb

15.0.16.2 Result:

change the familiarity value of the given social link

15.0.16.3 Examples:

```
social_link set_familiarity 0.4
```

15.0.17 set_intensity

15.0.17.1 Possible use:

- emotion **set_intensity** float —> emotion
- **set_intensity** (emotion , float) —> emotion

15.0.17.2 Result:

change the intensity value of the given emotion

15.0.17.3 Examples:

```
emotion set_intensity 12
```

15.0.18 set_lifetime

15.0.18.1 Possible use:

- mental_state **set_lifetime** int —> mental_state
- **set_lifetime** (mental_state , int) —> mental_state

15.0.18.2 Result:

change the lifetime value of the given mental state

15.0.18.3 Examples:

```
mental state set_lifetime 1
```

15.0.19 set_liking

15.0.19.1 Possible use:

- msi.gaml.architecture.simplebdi.SocialLink **set_liking** float —> msi.gaml.architecture.simplebdi.Soci
- **set_liking** (msi.gaml.architecture.simplebdi.SocialLink , float) —> msi.gaml.architecture.simplebdi.So

15.0.19.2 Result:

change the liking value of the given social link

15.0.19.3 Examples:

```
social_link set_liking 0.4
```

15.0.20 `set_modality`

15.0.20.1 Possible use:

- mental_state **set_modality** string —> mental_state
- **set_modality** (mental_state , string) —> mental_state

15.0.20.2 Result:

change the modality value of the given mental state

15.0.20.3 Examples:

```
mental state set_modality belief
```

15.0.21 `set_predicate`

15.0.21.1 Possible use:

- mental_state **set_predicate** predicate —> mental_state
- **set_predicate** (mental_state , predicate) —> mental_state

15.0.21.2 Result:

change the predicate value of the given mental state

15.0.21.3 Examples:

```
mental state set_predicate pred1
```

15.0.22 `set_solidarity`

15.0.22.1 Possible use:

- msi.gaml.architecture.simplebdi.SocialLink **set_solidarity** float —> msi.gaml.architecture.simplebdi.S
- **set_solidarity** (msi.gaml.architecture.simplebdi.SocialLink , float) —> msi.gaml.architecture.simplebd

15.0.22.2 Result:

change the solidarity value of the given social link

15.0.22.3 Examples:

```
social_link set_solidarity 0.4
```

15.0.23   set_strength

15.0.23.1   Possible use:

- mental_state **set_strength** float —> mental_state
- **set_strength** (mental_state , float) —> mental_state

15.0.23.2   Result:

change the strength value of the given mental state

15.0.23.3   Examples:

```
mental state set_strength 1.0
```

15.0.24   set_trust

15.0.24.1   Possible use:

- msi.gaml.architecture.simplebdi.SocialLink **set_trust** float —> msi.gaml.architecture.simplebdi.Social
- **set_trust** (msi.gaml.architecture.simplebdi.SocialLink , float) —> msi.gaml.architecture.simplebdi.Soc

15.0.24.2   Result:

change the trust value of the given social link

15.0.24.3   Examples:

```
social_link set_familiarity 0.4
```

15.0.25   set_truth

15.0.25.1   Possible use:

- predicate **set_truth** bool —> predicate
- **set_truth** (predicate , bool) —> predicate

15.0.25.2   Result:

change the is_true value of the given predicate

15.0.25.3   Examples:

```
predicate set_truth false
```

15.0.26 `set_z`

15.0.26.1 Possible use:

- geometry **set_z** container<float> —> geometry
- **set_z** (geometry , container<float>) —> geometry
- **set_z** (geometry, int, float) —> geometry

15.0.26.2 Result:

Sets the z ordinate of the n-th point of a geometry to the value provided by the third argument

15.0.26.3 Examples:

```
loop i from: 0 to: length(shape.points) - 1{set shape <-  set_z (shape, i, 3.0);} shape <- triangle(3)
```

15.0.27 `shape_file`

15.0.27.1 Possible use:

- **shape_file** (string) —> file

15.0.27.2 Result:

Constructs a file of type shape. Allowed extensions are limited to shp

---

15.0.28 `shuffle`

15.0.28.1 Possible use:

- **shuffle** (matrix) —> matrix
- **shuffle** (string) —> string
- **shuffle** (container) —> list

15.0.28.2 Result:

The elements of the operand in random order.

15.0.28.3 Special cases:

- if the operand is empty, returns an empty list (or string, matrix)

15.0.28.4   Examples:

```
matrix var0 <- shuffle (matrix([["c11","c12","c13"],["c21","c22","c23"]])); // var0 equals matrix([["c1:
string var1 <- shuffle ('abc'); // var1 equals 'bac' (for example)
list var2 <- shuffle ([12, 13, 14]); // var2 equals [14,12,13] (for example)
```

15.0.28.5   See also:

reverse,

15.0.29   signum

15.0.29.1   Possible use:

- **signum** (float) —> int

15.0.29.2   Result:

Returns -1 if the argument is negative, +1 if it is positive, 0 if it is equal to zero or not a number

15.0.29.3   Examples:

```
int var0 <- signum(-12); // var0 equals -1
int var1 <- signum(14); // var1 equals 1
int var2 <- signum(0); // var2 equals 0
```

15.0.30   simple_clustering_by_distance

15.0.30.1   Possible use:

- container<agent> **simple_clustering_by_distance** float —> list<list<agent>>
- **simple_clustering_by_distance** (container<agent> , float) —> list<list<agent>>

15.0.30.2   Result:

A list of agent groups clustered by distance considering a distance min between two groups.

15.0.30.3   Examples:

```
list<list<agent>> var0 <- [ag1, ag2, ag3, ag4, ag5] simpleClusteringByDistance 20.0; // var0 equals for
```

15.0.30.4   See also:

hierarchical_clustering,

15.0.31   simple_clustering_by_envelope_distance

Same signification as simple_clustering_by_distance

15.0.32   simplex_generator

15.0.32.1   Possible use:

- **simplex_generator** (float, float, float) —> float

15.0.32.2   Result:

take a x, y and a bias parameters and gives a value

15.0.32.3   Examples:

```
float var0 <- simplex_generator(2,3,253); // var0 equals 10.2
```

15.0.33   simplification

15.0.33.1   Possible use:

- geometry **simplification** float —> geometry
- **simplification** (geometry , float) —> geometry

15.0.33.2   Result:

A geometry corresponding to the simplification of the operand (geometry, agent, point) considering a tolerance distance.

15.0.33.3   Comment:

The algorithm used for the simplification is Douglas-Peucker

15.0.33.4 Examples:

```
geometry var0 <- self simplification 0.1; // var0 equals the geometry resulting from the application of
```

15.0.34 `sin`

15.0.34.1 Possible use:

- **sin** (float) —> float
- **sin** (int) —> float

15.0.34.2 Result:

Returns the value (in [-1,1]) of the sinus of the operand (in decimal degrees). The argument is casted to an int before being evaluated.

15.0.34.3 Special cases:

- Operand values out of the range [0-359] are normalized.

15.0.34.4 Examples:

```
float var0 <- sin(360) with_precision 10 with_precision 10; // var0 equals 0.0
float var1 <- sin (0); // var1 equals 0.0
```

15.0.34.5 See also:

cos, tan,

15.0.35 `sin_rad`

15.0.35.1 Possible use:

- **sin_rad** (float) —> float

15.0.35.2 Result:

Returns the value (in [-1,1]) of the sinus of the operand (in radians).

15.0.35.3 Examples:

```
float var0 <- sin_rad(#pi); // var0 equals 0.0
```

15.0.35.4   See also:

cos_rad, tan_rad,

15.0.36   `since`

15.0.36.1   Possible use:

- **since** (date) —> bool
- any expression **since** date —> bool
- **since** (any expression , date) —> bool

15.0.36.2   Result:

Returns true if the current_date of the model is after (or equal to) the date passed in argument. Synonym of 'current_date >= argument'. Can be used, like 'after', in its composed form with 2 arguments to express the lowest boundary of the computation of a frequency. However, contrary to 'after', there is a subtle difference: the lowest boundary will be tested against the frequency as well

15.0.36.3   Examples:

```
reflex when: since(starting_date) {}    // this reflex will always be run every(2#days) since (starting
```

15.0.37   `skeletonize`

15.0.37.1   Possible use:

- **skeletonize** (geometry) —> list<geometry>
- geometry **skeletonize** float —> list<geometry>
- **skeletonize** (geometry , float) —> list<geometry>
- **skeletonize** (geometry, float, float) —> list<geometry>
- **skeletonize** (geometry, float, float, bool) —> list<geometry>

15.0.37.2   Result:

A list of geometries (polylines) corresponding to the skeleton of the operand geometry (geometry, agent) with the given tolerance for the clipping and for the triangulation A list of geometries (polylines) corresponding to the skeleton of the operand geometry (geometry, agent) A list of geometries (polylines) corresponding to the skeleton of the operand geometry (geometry, agent) with the given tolerance for the clipping and for the triangulation A list of geometries (polylines) corresponding to the skeleton of the operand geometry (geometry, agent) with the given tolerance for the clipping

15.0.37.3   Examples:

```
list<geometry> var0 <- skeletonize(self); // var0 equals the list of geometries corresponding to the ske
list<geometry> var1 <- skeletonize(self); // var1 equals the list of geometries corresponding to the ske
list<geometry> var2 <- skeletonize(self); // var2 equals the list of geometries corresponding to the ske
list<geometry> var3 <- skeletonize(self); // var3 equals the list of geometries corresponding to the ske
```

15.0.38   `skew`

15.0.38.1   Possible use:

- **skew** (container) —> float
- float **skew** float —> float
- **skew** (float , float) —> float

15.0.38.2   Result:

Returns the skew of a data sequence, which is moment(data,3,mean) / standardDeviation3 Returns the skew of a data sequence.

15.0.39   `skew_gauss`

15.0.39.1   Possible use:

- **skew_gauss** (float, float, float, float) —> float

15.0.39.2   Result:

A value from a skew normally distributed random variable with min value (the minimum skewed value possible), max value (the maximum skewed value possible), skew (the degree to which the values cluster around the mode of the distribution; higher values mean tighter clustering) and bias (the tendency of the mode to approach the min, max or midpoint value; positive values bias toward max, negative values toward min).The algorithm was taken from http://stackoverflow.com/questions/5853187/skewing-java-random-number-generation-toward-a-certain-number

15.0.39.3   Examples:

```
float var0 <- skew_gauss(0.0, 1.0, 0.7,0.1); // var0 equals 0.1729218460343077
```

15.0.39.4   See also:

gauss, truncated_gauss, poisson,

15.0.40 skewness

15.0.40.1 Possible use:

- **skewness** (list) —> float

15.0.40.2 Result:

returns skewness value computed from the operand list of values

15.0.40.3 Special cases:

- if the length of the list is lower than 3, returns NaN

15.0.40.4 Examples:

```
float var0 <- skewness ([1,2,3,4,5]); // var0 equals 0.0
```

15.0.41 skill

15.0.41.1 Possible use:

- **skill** (any) —> skill

15.0.41.2 Result:

Casts the operand into the type skill

15.0.42 smooth

15.0.42.1 Possible use:

- geometry **smooth** float —> geometry
- **smooth** (geometry , float) —> geometry

15.0.42.2 Result:

Returns a 'smoothed' geometry, where straight lines are replaces by polynomial (bicubic) curves. The first parameter is the original geometry, the second is the 'fit' parameter which can be in the range 0 (loose fit) to 1 (tightest fit).

15.0.42.3 Examples:

```
geometry var0 <- smooth(square(10), 0.0); // var0 equals a 'rounded' square
```

15.0.43 social_link

15.0.43.1 Possible use:

- **social_link** (any) —> social_link

15.0.43.2 Result:

Casts the operand into the type social_link

15.0.44 solid

Same signification as without_holes

15.0.45 sort

Same signification as sort_by

15.0.46 sort_by

15.0.46.1 Possible use:

- container **sort_by** any expression —> list
- **sort_by** (container , any expression) —> list

15.0.46.2 Result:

Returns a list, containing the elements of the left-hand operand sorted in ascending order by the value of the right-hand operand when it is evaluated on them.

15.0.46.3 Comment:

the left-hand operand is casted to a list before applying the operator. In the right-hand operand, the keyword each can be used to represent, in turn, each of the elements.

15.0.46.4 Special cases:

- if the left-hand operand is nil, sort_by throws an error. If the sorting function returns values that cannot be compared, an error will be thrown as well

15.0.46.5 Examples:

```
list var0 <- [1,2,4,3,5,7,6,8] sort_by (each); // var0 equals [1,2,3,4,5,6,7,8]
list var2 <- g2 sort_by (length(g2 out_edges_of each) ); // var2 equals [node9, node7, node10, node8, n
list var3 <- (list(node) sort_by (round(node(each).location.x)); // var3 equals [node5, node1, node0, n
list var4 <- [1::2, 5::6, 3::4] sort_by (each); // var4 equals [2, 4, 6]
```

15.0.46.6 See also:

group_by,

15.0.47 source_of

15.0.47.1 Possible use:

- graph **source_of** unknown —> unknown
- **source_of** (graph , unknown) —> unknown

15.0.47.2 Result:

returns the source of the edge (right-hand operand) contained in the graph given in left-hand operand.

15.0.47.3 Special cases:

- if the lef-hand operand (the graph) is nil, throws an Exception

15.0.47.4 Examples:

```
graph graphEpidemio <- generate_barabasi_albert( ["edges_species"::edge,"vertices_specy"::node,"size"::3
unknown var1 <- graphEpidemio source_of(edge(3)); // var1 equals node1graph graphFromMap <-  as_edge_gr
point var3 <- graphFromMap source_of(link({1,5},{12,45})); // var3 equals {1,5}
```

15.0.47.5 See also:

target_of,

15.0.48 `spatial_graph`

15.0.48.1 Possible use:

- **spatial_graph** (container) —> graph

15.0.48.2 Result:

allows to create a spatial graph from a container of vertices, without trying to wire them. The container can be empty. Emits an error if the contents of the container are not geometries, points or agents

15.0.48.3 See also:

graph,

15.0.49 `species`

15.0.49.1 Possible use:

- **species** (unknown) —> species

15.0.49.2 Result:

casting of the operand to a species.

15.0.49.3 Special cases:

- if the operand is nil, returns nil;

- if the operand is an agent, returns its species;

- if the operand is a string, returns the species with this name (nil if not found);

- otherwise, returns nil

15.0.49.4 Examples:

```
species var0 <- species(self); // var0 equals the species of the current agent
species var1 <- species('node'); // var1 equals node
species var2 <- species([1,5,9,3]); // var2 equals nil
species var3 <- species(node1); // var3 equals node
```

15.0.50 `species_of`

Same signification as species

15.0.51 `sphere`

15.0.51.1 Possible use:

- **sphere** (float) —> geometry

15.0.51.2 Result:

A sphere geometry which radius is equal to the operand.

15.0.51.3 Comment:

the centre of the sphere is by default the location of the current agent in which has been called this operator.

15.0.51.4 Special cases:

- returns a point if the operand is lower or equal to 0.

15.0.51.5 Examples:

```
geometry var0 <- sphere(10); // var0 equals a geometry as a circle of radius 10 but displays a sphere.
```

15.0.51.6 See also:

around, cone, line, link, norm, point, polygon, polyline, rectangle, square, triangle,

---

15.0.52 `split`

15.0.52.1 Possible use:

- **split** (list) —> list<list>

15.0.52.2 Result:

Splits a list of numbers into n=(1+3.3*log10(elements)) bins. The splitting is strict (i.e. elements are in the ith bin if they are strictly smaller than the ith bound

15.0.52.3   See also:

split_in, split_using,

15.0.53   `split_at`

15.0.53.1   Possible use:

- geometry **split_at** point —> list<geometry>
- **split_at** (geometry , point) —> list<geometry>

15.0.53.2   Result:

The two part of the left-operand lines split at the given right-operand point

15.0.53.3   Special cases:

- if the left-operand is a point or a polygon, returns an empty list

15.0.53.4   Examples:

```
list<geometry> var0 <- polyline([{1,2},{4,6}]) split_at {7,6}; // var0 equals [polyline([{1.0,2.0},{7.0
```

15.0.54   `split_geometry`

15.0.54.1   Possible use:

- geometry **split_geometry** point —> list<geometry>
- **split_geometry** (geometry , point) —> list<geometry>
- geometry **split_geometry** float —> list<geometry>
- **split_geometry** (geometry , float) —> list<geometry>
- **split_geometry** (geometry, int, int) —> list<geometry>

15.0.54.2   Result:

A list of geometries that result from the decomposition of the geometry by rectangle cells of the given dimension (geometry, {size_x, size_y}) A list of geometries that result from the decomposition of the geometry according to a grid with the given number of rows and columns (geometry, nb_cols, nb_rows) A list of geometries that result from the decomposition of the geometry by square cells of the given side size (geometry, size)

15.0.54.3 Examples:

```
list<geometry> var0 <- to_rectangles(self, {10.0, 15.0}); // var0 equals the list of the geometries cor
list<geometry> var1 <- to_rectangles(self, 10,20); // var1 equals the list of the geometries correspond
list<geometry> var2 <- to_squares(self, 10.0); // var2 equals the list of the geometries corresponding
```

15.0.55 `split_in`

15.0.55.1 Possible use:

- list **split_in** int —> list<list>
- **split_in** (list , int) —> list<list>
- **split_in** (list, int, bool) —> list<list>

15.0.55.2 Result:

Splits a list of numbers into n bins defined by n-1 bounds between the minimum and maximum values found in the first argument. The boolean argument controls whether or not the splitting is strict (if true, elements are in the ith bin if they are strictly smaller than the ith bound Splits a list of numbers into n bins defined by n-1 bounds between the minimum and maximum values found in the first argument. The splitting is strict (i.e. elements are in the ith bin if they are strictly smaller than the ith bound

15.0.55.3 See also:

split, split_using,

15.0.56 `split_lines`

15.0.56.1 Possible use:

- **split_lines** (container<geometry>) —> list<geometry>
- container<geometry> **split_lines** bool —> list<geometry>
- **split_lines** (container<geometry> , bool) —> list<geometry>

15.0.56.2 Result:

A list of geometries resulting after cutting the lines at their intersections. if the last boolean operand is set to true, the split lines will import the attributes of the initial lines A list of geometries resulting after cutting the lines at their intersections.

15.0.56.3 Examples:

```
list<geometry> var0 <- split_lines([line([{0,10}, {20,10}]), line([{0,10}, {20,10}])]); // var0 equals a
list<geometry> var1 <- split_lines([line([{0,10}, {20,10}]), line([{0,10}, {20,10}])]); // var1 equals a
```

15.0.57 `split_using`

15.0.57.1 Possible use:

- list **split_using** msi.gama.util.IList<? extends java.lang.Comparable> —> list<list>
- **split_using** (list , msi.gama.util.IList<? extends java.lang.Comparable>) —> list<list>
- **split_using** (list, msi.gama.util.IList<? extends java.lang.Comparable>, bool) —> list<list>

15.0.57.2 Result:

Splits a list of numbers into n+1 bins using a set of n bounds passed as the second argument. The boolean argument controls whether or not the splitting is strict (if true, elements are in the ith bin if they are strictly smaller than the ith bound Splits a list of numbers into n+1 bins using a set of n bounds passed as the second argument. The splitting is strict (i.e. elements are in the ith bin if they are strictly smaller than the ith bound

15.0.57.3 See also:

split, split_in,

15.0.58 `split_with`

15.0.58.1 Possible use:

- string **split_with** string —> list
- **split_with** (string , string) —> list
- **split_with** (string, string, bool) —> list

15.0.58.2 Result:

Returns a list containing the sub-strings (tokens) of the left-hand operand delimited by each of the characters of the right-hand operand. Returns a list containing the sub-strings (tokens) of the left-hand operand delimited either by each of the characters of the right-hand operand (false) or by the whole right-hand operand (true).

15.0.58.3 Comment:

Delimiters themselves are excluded from the resulting list.Delimiters themselves are excluded from the resulting list.

15.0.58.4 Examples:

```
list var0 <- 'to be or not to be,that is the question' split_with ' ,'; // var0 equals ['to','be','or',
list var1 <- 'aa::bb:cc' split_with ('::', true); // var1 equals ['aa','bb:cc']
```

15.0.59 sqrt

15.0.59.1 Possible use:

- **sqrt** (int) —> float
- **sqrt** (float) —> float

15.0.59.2 Result:

Returns the square root of the operand.

15.0.59.3 Special cases:

- if the operand is negative, an exception is raised

15.0.59.4 Examples:

```
float var0 <- sqrt(4); // var0 equals 2.0
float var1 <- sqrt(4); // var1 equals 2.0
```

15.0.60 square

15.0.60.1 Possible use:

- **square** (float) —> geometry

15.0.60.2 Result:

A square geometry which side size is equal to the operand.

15.0.60.3 Comment:

the centre of the square is by default the location of the current agent in which has been called this operator.

15.0.60.4 Special cases:

- returns nil if the operand is nil.

15.0.60.5 Examples:

```
geometry var0 <- square(10); // var0 equals a geometry as a square of side size 10.
```

15.0.60.6 See also:

around, circle, cone, line, link, norm, point, polygon, polyline, rectangle, triangle,

---

15.0.61 `squircle`

15.0.61.1 Possible use:

- float **squircle** float —> geometry
- **squircle** (float , float) —> geometry

15.0.61.2 Result:

A mix of square and circle geometry (see : http://en.wikipedia.org/wiki/Squircle), which side size is equal to the first operand and power is equal to the second operand

15.0.61.3 Comment:

the center of the ellipse is by default the location of the current agent in which has been called this operator.

15.0.61.4 Special cases:

- returns a point if the side operand is lower or equal to 0.

15.0.61.5 Examples:

```
geometry var0 <- squircle(4,4); // var0 equals a geometry as a squircle of side 4 with a power of 4.
```

15.0.61.6 See also:

around, cone, line, link, norm, point, polygon, polyline, super_ellipse, rectangle, square, circle, ellipse, triangle,

---

15.0.62 `stack`

15.0.62.1 Possible use:

- **stack** (msi.gama.util.IList<java.lang.Integer>) —> msi.gama.util.tree.GamaNode<java.lang.String>

15.0.63 `standard_deviation`

15.0.63.1 Possible use:

- **standard_deviation** (container) —> float

15.0.63.2 Result:

the standard deviation on the elements of the operand. See Standard_deviation for more details.

15.0.63.3 Comment:

The operator casts all the numerical element of the list into float. The elements that are not numerical are discarded.

15.0.63.4 Examples:

```
float var0 <- standard_deviation ([4.5, 3.5, 5.5, 7.0]); // var0 equals 1.2930100540985752
```

15.0.63.5 See also:

mean, mean_deviation,

15.0.64 `step_sub_model`

15.0.64.1 Possible use:

- **step_sub_model** (msi.gama.kernel.experiment.IExperimentAgent) —> int

15.0.64.2 Result:

Load a submodel

15.0.64.3 Comment:

loaded submodel

15.0.65 `strahler`

15.0.65.1 Possible use:

- **strahler** (graph) —> map

15.0.65.2 Result:

retur for each edge, its strahler number

15.0.66 `string`

15.0.66.1 Possible use:

- date **string** string —> string
- **string** (date , string) —> string
- **string** (date, string, string) —> string

15.0.66.2 Result:

converts a date to astring following a custom pattern and using a specific locale (e.g.: 'fr', 'en', etc.). The pattern can use "%Y %M %N %D %E %h %m %s %z" for outputting years, months, name of month, days, name of days, hours, minutes, seconds and the time-zone. A null or empty pattern will return the complete date as defined by the ISO date & time format. The pattern can also follow the pattern definition found here, which gives much more control over the format of the date: https://docs.oracle.com/javase/8/docs/api/java/time/format/DateTimeFormatter.html#patterns. Different patterns are available by default as constants: #iso_local, #iso_simple, #iso_offset, #iso_zoned and #custom, which can be changed in the preferences converts a date to astring following a custom pattern. The pattern can use "%Y %M %N %D %E %h %m %s %z" for outputting years, months, name of month, days, name of days, hours, minutes, seconds and the time-zone. A null or empty pattern will return the complete date as defined by the ISO date & time format. The pattern can also follow the pattern definition found here, which gives much more control over the format of the date: https://docs.oracle.com/javase/8/docs/api/java/time/format/DateTimeFormatter.html#patterns. Different patterns are available by default as constants: #iso_local, #iso_simple, #iso_offset, #iso_zoned and #custom, which can be changed in the preferences

15.0.66.3 Examples:

```
format(#now, 'yyyy-MM-dd') format(#now, 'yyyy-MM-dd')
```

15.0.67 `student_area`

15.0.67.1 Possible use:

- float **student_area** int —> float
- **student_area** (float , int) —> float

15.0.67.2 Result:

Returns the area to the left of x in the Student T distribution with the given degrees of freedom.

15.0.68   `student_t_inverse`

15.0.68.1   Possible use:

- float **student_t_inverse** int —> float
- **student_t_inverse** (float , int) —> float

15.0.68.2   Result:

Returns the value, t, for which the area under the Student-t probability density function (integrated from minus infinity to t) is equal to x.

15.0.69   `subtract_days`

Same signification as minus_days

15.0.70   `subtract_hours`

Same signification as minus_hours

15.0.71   `subtract_minutes`

Same signification as minus_minutes

15.0.72   `subtract_months`

Same signification as minus_months

15.0.73   `subtract_ms`

Same signification as minus_ms

15.0.74   `subtract_seconds`

Same signification as -

15.0.75 `subtract_weeks`

Same signification as minus_weeks

15.0.76 `subtract_years`

Same signification as minus_years

15.0.77 `successors_of`

15.0.77.1 Possible use:

- graph **`successors_of`** unknown —> list
- **`successors_of`** (graph , unknown) —> list

15.0.77.2 Result:

returns the list of successors (i.e. targets of out edges) of the given vertex (right-hand operand) in the given graph (left-hand operand)

15.0.77.3 Examples:

```
list var1 <- graphEpidemio successors_of ({1,5}); // var1 equals [{12,45}]
list var2 <- graphEpidemio successors_of node({34,56}); // var2 equals []
```

15.0.77.4 See also:

predecessors_of, neighbors_of,

15.0.78 `sum`

15.0.78.1 Possible use:

- **`sum`** (graph) —> float
- **`sum`** (container) —> unknown

15.0.78.2 Result:

the sum of all the elements of the operand

15.0.78.3 Comment:

the behavior depends on the nature of the operand

15.0.78.4 Special cases:

- if it is a population or a list of other types: sum transforms all elements into float and sums them

- if it is a map, sum returns the sum of the value of all elements

- if it is a file, sum returns the sum of the content of the file (that is also a container)

- if it is a graph, sum returns the total weight of the graph

- if it is a matrix of int, float or object, sum returns the sum of all the numerical elements (i.e. all elements for integer and float matrices)

- if it is a matrix of other types: sum transforms all elements into float and sums them

- if it is a list of colors: sum will sum them and return the blended resulting color

- if it is a list of int or float: sum returns the sum of all the elements

```
int var0 <- sum ([12,10,3]); // var0 equals 25
```

- if it is a list of points: sum returns the sum of all points as a point (each coordinate is the sum of the corresponding coordinate of each element)

```
unknown var1 <- sum([{1.0,3.0},{3.0,5.0},{9.0,1.0},{7.0,8.0}]); // var1 equals {20.0,17.0}
```

15.0.78.5 See also:

mul,

15.0.79 sum_of

15.0.79.1 Possible use:

- container **sum_of** any expression —> unknown
- **sum_of** (container , any expression) —> unknown

15.0.79.2 Result:

the sum of the right-hand expression evaluated on each of the elements of the left-hand operand

15.0.79.3   Comment:

in the right-hand operand, the keyword each can be used to represent, in turn, each of the right-hand operand elements.

15.0.79.4   Special cases:

- if the left-operand is a map, the keyword each will contain each value

```
unknown var1 <- [1::2, 3::4, 5::6] sum_of (each + 3); // var1 equals 21
```

15.0.79.5   Examples:

```
unknown var0 <- [1,2] sum_of (each * 100 ); // var0 equals 300
```

15.0.79.6   See also:

min_of, max_of, product_of, mean_of,

15.0.80   `svg_file`

15.0.80.1   Possible use:

- **svg_file** (string) —> file

15.0.80.2   Result:

Constructs a file of type svg. Allowed extensions are limited to svg

---

15.0.81   `tan`

15.0.81.1   Possible use:

- **tan** (int) —> float
- **tan** (float) —> float

15.0.81.2   Result:

Returns the value (in [-1,1]) of the trigonometric tangent of the operand (in decimal degrees).

15.0.81.3 Special cases:

- Operand values out of the range [0-359] are normalized. Notice that tan(360) does not return 0.0 but -2.4492935982947064E-16

- The tangent is only defined for any real number except $90 + k * 180$ (k an positive or negative integer). Nevertheless notice that tan(90) returns 1.633123935319537E16 (whereas we could except infinity).

15.0.81.4 Examples:

```
float var0 <- tan (0); // var0 equals 0.0
float var1 <- tan(90); // var1 equals 1.633123935319537E16
```

15.0.81.5 See also:

cos, sin,

15.0.82 tan_rad

15.0.82.1 Possible use:

- **tan_rad** (float) —> float

15.0.82.2 Result:

Returns the value (in [-1,1]) of the trigonometric tangent of the operand (in radians).

15.0.82.3 See also:

cos_rad, sin_rad,

15.0.83 tanh

15.0.83.1 Possible use:

- **tanh** (int) —> float
- **tanh** (float) —> float

15.0.83.2 Result:

Returns the value (in the interval [-1,1]) of the hyperbolic tangent of the operand (which can be any real number, expressed in decimal degrees).

15.0.83.3 Examples:

```
float var0 <- tanh(0); // var0 equals 0.0
float var1 <- tanh(100); // var1 equals 1.0
```

15.0.84 `target_of`

15.0.84.1 Possible use:

- graph **target_of** unknown —> unknown
- **target_of** (graph , unknown) —> unknown

15.0.84.2 Result:

returns the target of the edge (right-hand operand) contained in the graph given in left-hand operand.

15.0.84.3 Special cases:

- if the lef-hand operand (the graph) is nil, returns nil

15.0.84.4 Examples:

```
graph graphEpidemio <- generate_barabasi_albert( ["edges_species"::edge,"vertices_specy"::node,"size"::3
unknown var1 <- graphEpidemio source_of(edge(3)); // var1 equals node1graph graphFromMap <-  as_edge_gra
unknown var3 <- graphFromMap target_of(link({1,5},{12,45})); // var3 equals {12,45}
```

15.0.84.5 See also:

source_of,

15.0.85 `teapot`

15.0.85.1 Possible use:

- **teapot** (float) —> geometry

15.0.85.2 Result:

A teapot geometry which radius is equal to the operand.

15.0.85.3 Comment:

the centre of the teapot is by default the location of the current agent in which has been called this operator.

15.0.85.4 Special cases:

- returns a point if the operand is lower or equal to 0.

15.0.85.5 Examples:

```
geometry var0 <- teapot(10); // var0 equals a geometry as a circle of radius 10 but displays a teapot.
```

15.0.85.6 See also:

around, cone, line, link, norm, point, polygon, polyline, rectangle, square, triangle,

---

15.0.86 text_file

15.0.86.1 Possible use:

- **text_file** (string) —> file

15.0.86.2 Result:

Constructs a file of type text. Allowed extensions are limited to txt, data, text

---

15.0.87 TGauss

Same signification as truncated_gauss

15.0.88 threeds_file

15.0.88.1 Possible use:

- **threeds_file** (string) —> file

15.0.88.2 Result:

Constructs a file of type threeds. Allowed extensions are limited to 3ds, max

---

15.0.89 to

15.0.89.1 Possible use:

- date **to** date —> msi.gama.util.IList<msi.gama.util.GamaDate>
- **to** (date , date) —> msi.gama.util.IList<msi.gama.util.GamaDate>

15.0.89.2 Result:

builds an interval between two dates (the first inclusive and the second exclusive, which behaves like a read-only list of dates. The default step between two dates is the step of the model

15.0.89.3 Comment:

The default step can be overruled by using the every operator applied to this interval

15.0.89.4 Examples:

date('2000-01-01') to date('2010-01-01') // builds an interval between these two dates (date('2000-01-0

15.0.89.5 See also:

every,

15.0.90 to_GAMA_CRS

15.0.90.1 Possible use:

- **to_GAMA_CRS** (geometry) —> geometry
- geometry **to_GAMA_CRS** string —> geometry
- **to_GAMA_CRS** (geometry , string) —> geometry

15.0.90.2 Special cases:

- returns the geometry corresponding to the transformation of the given geometry to the GAMA CRS (Coordinate Reference System) assuming the given geometry is referenced by given CRS

geometry var0 <- to_GAMA_CRS({121,14}, "EPSG:4326"); // var0 equals a geometry corresponding to the age

- returns the geometry corresponding to the transformation of the given geometry to the GAMA CRS (Coordinate Reference System) assuming the given geometry is referenced by the current CRS, the one corresponding to the world's agent one

geometry var1 <- to_GAMA_CRS({121,14}); // var1 equals a geometry corresponding to the agent geometry t:

15.0.91 `to_gaml`

15.0.91.1 Possible use:

- **to_gaml** (unknown) —> string

15.0.91.2 Result:

returns the literal description of an expression or description – action, behavior, species, aspect, even model – in gaml

15.0.91.3 Examples:

```
string var0 <- to_gaml(0); // var0 equals '0'
string var1 <- to_gaml(3.78); // var1 equals '3.78'
string var2 <- to_gaml(true); // var2 equals 'true'
string var3 <- to_gaml({23, 4.0}); // var3 equals '{23.0,4.0,0.0}'
string var4 <- to_gaml(5::34); // var4 equals '5::34'
string var5 <- to_gaml(rgb(255,0,125)); // var5 equals 'rgb (255, 0, 125,255)'
string var6 <- to_gaml('hello'); // var6 equals "'hello'"
string var7 <- to_gaml([1,5,9,3]); // var7 equals '[1,5,9,3]'
string var8 <- to_gaml(['a'::345, 'b'::13, 'c'::12]); // var8 equals "map(['a'::345,'b'::13,'c'::12])"
string var9 <- to_gaml([[3,5,7,9],[2,4,6,8]]); // var9 equals '[[3,5,7,9],[2,4,6,8]]'
string var10 <- to_gaml(a_graph); // var10 equals ([((1 as node)::(3 as node))::(5 as edge),((0 as node)
string var11 <- to_gaml(node1); // var11 equals  1 as node
```

15.0.92 `to_rectangles`

Same signification as split_geometry

15.0.92.1 Possible use:

- **to_rectangles** (geometry, point, bool) —> list<geometry>
- **to_rectangles** (geometry, int, int, bool) —> list<geometry>

15.0.92.2 Result:

A list of rectangles corresponding to the given dimension that result from the decomposition of the geometry into rectangles (geometry, nb_cols, nb_rows, overlaps) by a grid composed of the given number of columns and rows, if overlaps = true, add the rectangles that overlap the border of the geometry A list of rectangles of the size corresponding to the given dimension that result from the decomposition of the geometry into rectangles (geometry, dimension, overlaps), if overlaps = true, add the rectangles that overlap the border of the geometry

15.0.92.3   Examples:

```
list<geometry> var0 <- to_rectangles(self, 5, 20, true); // var0 equals the list of rectangles correspo
list<geometry> var1 <- to_rectangles(self, {10.0, 15.0}, true); // var1 equals the list of rectangles o
```

15.0.93   to_squares

15.0.93.1   Possible use:

- **to_squares** (geometry, int, bool) —> list<geometry>
- **to_squares** (geometry, float, bool) —> list<geometry>
- **to_squares** (geometry, int, bool, float) —> list<geometry>

15.0.93.2   Result:

A list of a given number of squares from the decomposition of the geometry into squares (geometry, nb_square, overlaps, precision_coefficient), if overlaps = true, add the squares that overlap the border of the geometry, coefficient_precision should be close to 1.0 A list of a given number of squares from the decomposition of the geometry into squares (geometry, nb_square, overlaps), if overlaps = true, add the squares that overlap the border of the geometry A list of squares of the size corresponding to the given size that result from the decomposition of the geometry into squares (geometry, size, overlaps), if overlaps = true, add the squares that overlap the border of the geometry

15.0.93.3   Examples:

```
list<geometry> var0 <- to_squares(self, 10, true, 0.99); // var0 equals the list of 10 squares correspo
list<geometry> var1 <- to_squares(self, 10, true); // var1 equals the list of 10 squares corresponding
list<geometry> var2 <- to_squares(self, 10.0, true); // var2 equals the list of squares of side size 10
```

15.0.94   to_sub_geometries

15.0.94.1   Possible use:

- geometry **to_sub_geometries** list<float> —> list<geometry>
- **to_sub_geometries** (geometry , list<float>) —> list<geometry>
- **to_sub_geometries** (geometry, list<float>, float) —> list<geometry>

15.0.94.2   Result:

A list of geometries resulting after spliting the geometry into sub-geometries. A list of geometries resulting after spliting the geometry into sub-geometries.

15.0.94.3 Examples:

```
list<geometry> var0 <- to_sub_geometries(rectangle(10, 50), [0.1, 0.5, 0.4], 1.0); // var0 equals a lis
list<geometry> var1 <- to_sub_geometries(rectangle(10, 50), [0.1, 0.5, 0.4]); // var1 equals a list of
```

15.0.95 to_triangles

Same signification as triangulate

15.0.96 tokenize

Same signification as split_with

15.0.97 topology

15.0.97.1 Possible use:

- **topology** (unknown) —> topology

15.0.97.2 Result:

casting of the operand to a topology.

15.0.97.3 Special cases:

- if the operand is a topology, returns the topology itself;

- if the operand is a spatial graph, returns the graph topology associated;

- if the operand is a population, returns the topology of the population;

- if the operand is a shape or a geometry, returns the continuous topology bounded by the geometry;

- if the operand is a matrix, returns the grid topology associated

- if the operand is another kind of container, returns the multiple topology associated to the container

- otherwise, casts the operand to a geometry and build a topology from it.

15.0.97.4 Examples:

```
topology var0 <- topology(0); // var0 equals niltopology(a_graph)   --: Multiple topology in POLYGON ((
```

15.0.97.5   See also:

geometry,

15.0.98   `topology`

15.0.98.1   Possible use:

- **topology** (any) —> topology

15.0.98.2   Result:

Casts the operand into the type topology

15.0.99   `touches`

15.0.99.1   Possible use:

- geometry **touches** geometry —> bool
- **touches** (geometry , geometry) —> bool

15.0.99.2   Result:

A boolean, equal to true if the left-geometry (or agent/point) touches the right-geometry (or agent/point).

15.0.99.3   Comment:

returns true when the left-operand only touches the right-operand. When one geometry covers partially (or fully) the other one, it returns false.

15.0.99.4   Special cases:

- if one of the operand is null, returns false.

15.0.99.5   Examples:

```
bool var0 <- polyline([{10,10},{20,20}]) touches {15,15}; // var0 equals false
bool var1 <- polyline([{10,10},{20,20}]) touches {10,10}; // var1 equals true
bool var2 <- {15,15} touches {15,15}; // var2 equals false
bool var3 <- polyline([{10,10},{20,20}]) touches polyline([{10,10},{5,5}]); // var3 equals true
bool var4 <- polyline([{10,10},{20,20}]) touches polyline([{5,5},{15,15}]); // var4 equals false
bool var5 <- polyline([{10,10},{20,20}]) touches polyline([{15,15},{25,25}]); // var5 equals false
bool var6 <- polygon([{10,10},{10,20},{20,20},{20,10}]) touches polygon([{15,15},{15,25},{25,25},{25,15]
bool var7 <- polygon([{10,10},{10,20},{20,20},{20,10}]) touches polygon([{10,20},{20,20},{20,30},{10,30]
bool var8 <- polygon([{10,10},{10,20},{20,20},{20,10}]) touches polygon([{10,10},{0,10},{0,0},{10,0}]);
```

```
bool var9 <- polygon([{10,10},{10,20},{20,20},{20,10}]) touches {15,15}; // var9 equals false
bool var10 <- polygon([{10,10},{10,20},{20,20},{20,10}]) touches {10,15}; // var10 equals true
```

15.0.99.6   See also:

disjoint_from, crosses, overlaps, partially_overlaps, intersects,

---

15.0.100   `towards`

15.0.100.1   Possible use:

- geometry **towards** geometry —> float
- **towards** (geometry , geometry) —> float

15.0.100.2   Result:

The direction (in degree) between the two geometries (geometries, agents, points) considering the topology
of the agent applying the operator.

15.0.100.3   Examples:

```
float var0 <- ag1 towards ag2; // var0 equals the direction between ag1 and ag2 and ag3 considering the
```

15.0.100.4   See also:

distance_between, distance_to, direction_between, path_between, path_to,

---

15.0.101   `trace`

15.0.101.1   Possible use:

- **trace** (matrix) —> float

15.0.101.2   Result:

The trace of the given matrix (the sum of the elements on the main diagonal).

15.0.101.3   Examples:

```
float var0 <- trace(matrix([[1,2],[3,4]])); // var0 equals 5
```

15.0.102 `transformed_by`

15.0.102.1 Possible use:

- geometry **transformed_by** point —> geometry
- **transformed_by** (geometry , point) —> geometry

15.0.102.2 Result:

A geometry resulting from the application of a rotation and a scaling (right-operand : point {angle(degree), scale factor} of the left-hand operand (geometry, agent, point)

15.0.102.3 Examples:

```
geometry var0 <- self transformed_by {45, 0.5}; // var0 equals the geometry resulting from 45 degrees r
```

15.0.102.4 See also:

rotated_by, translated_by,

15.0.103 `translated_by`

15.0.103.1 Possible use:

- geometry **translated_by** point —> geometry
- **translated_by** (geometry , point) —> geometry

15.0.103.2 Result:

A geometry resulting from the application of a translation by the right-hand operand distance to the left-hand operand (geometry, agent, point)

15.0.103.3 Examples:

```
geometry var0 <- self translated_by {10,10,10}; // var0 equals the geometry resulting from applying the
```

15.0.103.4 See also:

rotated_by, transformed_by,

15.0.104 `translated_to`

Same signification as at_location

15.0.105 `transpose`

15.0.105.1 Possible use:

- **transpose** (matrix) —> matrix

15.0.105.2 Result:

The transposition of the given matrix

15.0.105.3 Examples:

```
matrix var0 <- transpose(matrix([[5,-3],[6,-4]])); // var0 equals matrix([[5,6],[-3,-4]])
```

15.0.106 `triangle`

15.0.106.1 Possible use:

- **triangle** (float) —> geometry

15.0.106.2 Result:

A triangle geometry which side size is given by the operand.

15.0.106.3 Comment:

the center of the triangle is by default the location of the current agent in which has been called this operator.

15.0.106.4 Special cases:

- returns nil if the operand is nil.

15.0.106.5 Examples:

```
geometry var0 <- triangle(5); // var0 equals a geometry as a triangle with side_size = 5.
```

15.0.106.6   See also:

around, circle, cone, line, link, norm, point, polygon, polyline, rectangle, square,

---

15.0.107   `triangulate`

15.0.107.1   Possible use:

- **triangulate** (geometry) —> list<geometry>
- **triangulate** (list<geometry>) —> list<geometry>
- geometry **triangulate** float —> list<geometry>
- **triangulate** (geometry , float) —> list<geometry>
- **triangulate** (geometry, float, float) —> list<geometry>
- **triangulate** (geometry, float, float, bool) —> list<geometry>

15.0.107.2   Result:

A list of geometries (triangles) corresponding to the Delaunay triangulation of the operand geometry (geometry, agent, point) A list of geometries (triangles) corresponding to the Delaunay triangulation of the operand geometry (geometry, agent, point) with the given tolerance for the clipping and for the triangulation A list of geometries (triangles) corresponding to the Delaunay triangulation of the operand geometry (geometry, agent, point) with the given tolerance for the clipping A list of geometries (triangles) corresponding to the Delaunay triangulation computed from the list of polylines A list of geometries (triangles) corresponding to the Delaunay triangulation of the operand geometry (geometry, agent, point, use_approx_clipping) with the given tolerance for the clipping and for the triangulation with using an approximate clipping is the last operand is true

15.0.107.3   Examples:

```
list<geometry> var0 <- triangulate(self); // var0 equals the list of geometries (triangles) correspondi
list<geometry> var1 <- triangulate(self,0.1, 1.0); // var1 equals the list of geometries (triangles) co
list<geometry> var2 <- triangulate(self, 0.1); // var2 equals the list of geometries (triangles) corresp
list<geometry> var3 <- triangulate([line([{0,50},{100,50}]), line([{50,0},{50,100}])); // var3 equals tl
list<geometry> var4 <- triangulate(self,0.1, 1.0); // var4 equals the list of geometries (triangles) co
```

15.0.108   `truncated_gauss`

15.0.108.1   Possible use:

- **truncated_gauss** (point) —> float
- **truncated_gauss** (list) —> float

15.0.108.2   Result:

A random value from a normally distributed random variable in the interval]mean - standardDeviation; mean + standardDeviation[.

15.0.108.3 Special cases:

- when the operand is a point, it is read as {mean, standardDeviation}

- if the operand is a list, only the two first elements are taken into account as [mean, standardDeviation]

- when truncated_gauss is called with a list of only one element mean, it will always return 0.0

15.0.108.4 Examples:

```
float var0 <- truncated_gauss ({0, 0.3}); // var0 equals a float between -0.3 and 0.3
float var1 <- truncated_gauss ([0.5, 0.0]); // var1 equals 0.5
```

15.0.108.5 See also:

gauss,

15.0.109 type_of

15.0.109.1 Possible use:

- type_of (unknown) —> msi.gaml.types.IType<?>

15.0.110 undirected

15.0.110.1 Possible use:

- undirected (graph) —> graph

15.0.110.2 Result:

the operand graph becomes an undirected graph.

15.0.110.3 Comment:

the operator alters the operand graph, it does not create a new one.

15.0.110.4 See also:

directed,

15.0.111   union

15.0.111.1   Possible use:

- **union** (container<geometry>) —> geometry
- container **union** container —> list
- **union** (container , container) —> list

15.0.111.2   Result:

returns a new list containing all the elements of both containers without duplicated elements.

15.0.111.3   Special cases:

- if the left or right operand is nil, union throws an error

- if the right-operand is a container of points, geometries or agents, returns the geometry resulting from the union all the geometries

15.0.111.4   Examples:

```
list var0 <- [1,2,3,4,5,6] union [2,4,9]; // var0 equals [1,2,3,4,5,6,9]
list var1 <- [1,2,3,4,5,6] union [0,8]; // var1 equals [1,2,3,4,5,6,0,8]
list var2 <- [1,3,2,4,5,6,8,5,6] union [0,8]; // var2 equals [1,3,2,4,5,6,8,0]
geometry var3 <- union([geom1, geom2, geom3]); // var3 equals a geometry corresponding to union between
```

15.0.111.5   See also:

inter, +,

15.0.112   unknown

15.0.112.1   Possible use:

- **unknown** (any) —> unknown

15.0.112.2   Result:

Casts the operand into the type unknown

15.0.113 `until`

15.0.113.1 Possible use:

- `until` (date) —> `bool`
- `any expression` `until` `date` —> `bool`
- `until` (any expression , date) —> `bool`

15.0.113.2 Result:

Returns true if the current_date of the model is before (or equel to) the date passed in argument. Synonym of 'current_date <= argument'

15.0.113.3 Examples:

```
reflex when: until(starting_date) {}    // This reflex will be run only once at the beginning of the sim
```

15.0.114 `upper_case`

15.0.114.1 Possible use:

- `upper_case` (string) —> `string`

15.0.114.2 Result:

Converts all of the characters in the string operand to upper case

15.0.114.3 Examples:

```
string var0 <- upper_case("Abc"); // var0 equals 'ABC'
```

15.0.114.4 See also:

lower_case,

15.0.115 `URL_file`

15.0.115.1 Possible use:

- `URL_file` (string) —> `file`

15.0.115.2   Result:

Constructs a file of type URL. Allowed extensions are limited to url

---

15.0.116   `use_cache`

15.0.116.1   Possible use:

- `graph` **`use_cache`** `bool` —> `graph`
- **`use_cache`** `(graph , bool)` —> `graph`

15.0.116.2   Result:

if the second operand is true, the operand graph will store in a cache all the previously computed shortest path (the cache be cleared if the graph is modified).

15.0.116.3   Comment:

the operator alters the operand graph, it does not create a new one.

15.0.116.4   See also:

path_between,

15.0.117   `user_input`

15.0.117.1   Possible use:

- **`user_input`** `(any expression)` —> `map<string,unknown>`
- `string` **`user_input`** `any expression` —> `map<string,unknown>`
- **`user_input`** `(string , any expression)` —> `map<string,unknown>`

15.0.117.2   Result:

asks the user for some values (not defined as parameters). Takes a string (optional) and a map as arguments. The string is used to specify the message of the dialog box. The map is to specify the parameters you want the user to change before the simulation starts, with the name of the parameter in string key, and the default value as value.

15.0.117.3   Comment:

This operator takes a map [string::value] as argument, displays a dialog asking the user for these values, and returns the same map with the modified values (if any). The dialog is modal and will interrupt the execution of the simulation until the user has either dismissed or accepted it. It can be used, for instance, in an init section to force the user to input new values instead of relying on the initial values of parameters :

15.0.117.4 Examples:

```
map<string,unknown> values <- user_input(["Number" :: 100, "Location" :: {10, 10}]); create bug number:
```

15.0.118 using

15.0.118.1 Possible use:

- `any expression` **using** `topology` —> unknown
- **using** (`any expression` , `topology`) —> unknown

15.0.118.2 Result:

Allows to specify in which topology a spatial computation should take place.

15.0.118.3 Special cases:

- has no effect if the topology passed as a parameter is nil

15.0.118.4 Examples:

```
unknown var0 <- (agents closest_to self) using topology(world); // var0 equals the closest agent to self
```

15.0.119 variance

15.0.119.1 Possible use:

- **variance** (`container`) —> float

15.0.119.2 Result:

the variance of the elements of the operand. See Variance for more details.

15.0.119.3 Comment:

The operator casts all the numerical element of the list into float. The elements that are not numerical are discarded.

15.0.119.4 Examples:

```
float var0 <- variance ([4.5, 3.5, 5.5, 7.0]); // var0 equals 1.671875
```

15.0.119.5   See also:

mean, median,

15.0.120   `variance`

15.0.120.1   Possible use:

- **variance** (float) —> float
- **variance** (int, float, float) —> float

15.0.120.2   Result:

Returns the variance from a standard deviation. Returns the variance of a data sequence. That is (sumOf-Squares - mean*sum) / size with mean = sum/size.

15.0.121   `variance_of`

15.0.121.1   Possible use:

- container **variance_of** any expression —> unknown
- **variance_of** (container , any expression) —> unknown

15.0.121.2   Result:

the variance of the right-hand expression evaluated on each of the elements of the left-hand operand

15.0.121.3   Comment:

in the right-hand operand, the keyword each can be used to represent, in turn, each of the right-hand operand elements.

15.0.121.4   See also:

min_of, max_of, sum_of, product_of,

15.0.122   `vertical`

15.0.122.1   Possible use:

- **vertical** (msi.gama.util.GamaMap<java.lang.Object,java.lang.Integer>) —> msi.gama.util.tree.GamaNode<

15.0.123 voronoi

15.0.123.1 Possible use:

- **voronoi** (list<point>) —> list<geometry>
- list<point> **voronoi** geometry —> list<geometry>
- **voronoi** (list<point> , geometry) —> list<geometry>

15.0.123.2 Result:

A list of geometries corresponding to the Voronoi diagram built from the list of points A list of geometries corresponding to the Voronoi diagram built from the list of points according to the given clip

15.0.123.3 Examples:

```
list<geometry> var0 <- voronoi([{10,10},{50,50},{90,90},{10,90},{90,10}]); // var0 equals the list of g
list<geometry> var1 <- voronoi([{10,10},{50,50},{90,90},{10,90},{90,10}], square(300)); // var1 equals
```

15.0.124 weight_of

15.0.124.1 Possible use:

- graph **weight_of** unknown —> float
- **weight_of** (graph , unknown) —> float

15.0.124.2 Result:

returns the weight of the given edge (right-hand operand) contained in the graph given in right-hand operand.

15.0.124.3 Comment:

In a localized graph, an edge has a weight by default (the distance between both vertices).

15.0.124.4 Special cases:

- if the left-operand (the graph) is nil, returns nil

- if the right-hand operand is not an edge of the given graph, weight_of checks whether it is a node of the graph and tries to return its weight

- if the right-hand operand is neither a node, nor an edge, returns 1.

15.0.124.5 Examples:

```
graph graphFromMap <-  as_edge_graph([{1,5}::{12,45},{12,45}::{34,56}]);
float var1 <- graphFromMap weight_of(link({1,5},{12,45})); // var1 equals 1.0
```

15.0.125 `weighted_means_DM`

15.0.125.1 Possible use:

- msi.gama.util.IList<java.util.List> **weighted_means_DM** msi.gama.util.IList<java.util.Map<java.lang.St
  —> int
- **weighted_means_DM** (msi.gama.util.IList<java.util.List> , msi.gama.util.IList<java.util.Map<java.lang.
  —> int

15.0.125.2 Result:

The index of the candidate that maximizes the weighted mean of its criterion values. The first operand is
the list of candidates (a candidate is a list of criterion values); the second operand the list of criterion (list
of map)

15.0.125.3 Special cases:

- returns -1 is the list of candidates is nil or empty

15.0.125.4 Examples:

```
int var0 <- weighted_means_DM([[1.0, 7.0],[4.0,2.0],[3.0, 3.0]], [["name"::"utility", "weight" :: 2.0],
```

15.0.125.5 See also:

promethee_DM, electre_DM, evidence_theory_DM,

15.0.126 `where`

15.0.126.1 Possible use:

- container **where** any expression —> list
- **where** (container , any expression) —> list

15.0.126.2 Result:

a list containing all the elements of the left-hand operand that make the right-hand operand evaluate to
true.

15.0.126.3   Comment:

in the right-hand operand, the keyword each can be used to represent, in turn, each of the right-hand operand elements.

15.0.126.4   Special cases:

- if the left-hand operand is a list nil, where returns a new empty list

- if the left-operand is a map, the keyword each will contain each value

```
list var4 <- [1::2, 3::4, 5::6] where (each >= 4); // var4 equals [4, 6]
```

15.0.126.5   Examples:

```
list var0 <- [1,2,3,4,5,6,7,8] where (each > 3); // var0 equals [4, 5, 6, 7, 8]
list var2 <- g2 where (length(g2 out_edges_of each) = 0 ); // var2 equals [node9, node7, node10, node8,
list var3 <- (list(node) where (round(node(each).location.x) > 32); // var3 equals [node2, node3]
```

15.0.126.6   See also:

first_with, last_with, where,

15.0.127   `with_lifetime`

15.0.127.1   Possible use:

- predicate **with_lifetime** int —> predicate
- **with_lifetime** (predicate , int) —> predicate

15.0.127.2   Result:

change the parameters of the given predicate

15.0.127.3   Examples:

```
predicate with_lifetime 10
```

15.0.128   `with_max_of`

15.0.128.1   Possible use:

- container **with_max_of** any expression —> unknown
- **with_max_of** (container , any expression) —> unknown

15.0.128.2 Result:

one of elements of the left-hand operand that maximizes the value of the right-hand operand

15.0.128.3 Comment:

in the right-hand operand, the keyword each can be used to represent, in turn, each of the right-hand operand elements.

15.0.128.4 Special cases:

- if the left-hand operand is nil, with_max_of returns the default value of the right-hand operand

15.0.128.5 Examples:

```
unknown var0 <- [1,2,3,4,5,6,7,8] with_max_of (each ); // var0 equals 8
unknown var2 <- g2 with_max_of (length(g2 out_edges_of each)  ) ; // var2 equals node4
unknown var3 <- (list(node) with_max_of (round(node(each).location.x)); // var3 equals node3
unknown var4 <- [1::2, 3::4, 5::6] with_max_of (each); // var4 equals 6
```

15.0.128.6 See also:

where, with_min_of,

15.0.129   with_min_of

15.0.129.1 Possible use:

- container **with_min_of** any expression —> unknown
- **with_min_of** (container , any expression) —> unknown

15.0.129.2 Result:

one of elements of the left-hand operand that minimizes the value of the right-hand operand

15.0.129.3 Comment:

in the right-hand operand, the keyword each can be used to represent, in turn, each of the right-hand operand elements.

15.0.129.4 Special cases:

- if the left-hand operand is nil, with_max_of returns the default value of the right-hand operand

15.0.129.5 Examples:

```
unknown var0 <- [1,2,3,4,5,6,7,8] with_min_of (each ); // var0 equals 1
unknown var2 <- g2 with_min_of (length(g2 out_edges_of each)  ); // var2 equals node11
unknown var3 <- (list(node) with_min_of (round(node(each).location.x)); // var3 equals node0
unknown var4 <- [1::2, 3::4, 5::6] with_min_of (each); // var4 equals 2
```

15.0.129.6 See also:

where, with_max_of,

15.0.130 `with_optimizer_type`

15.0.130.1 Possible use:

- graph **with_optimizer_type** string —> graph
- **with_optimizer_type** (graph , string) —> graph

15.0.130.2 Result:

changes the shortest path computation method of the given graph

15.0.130.3 Comment:

the right-hand operand can be "Djikstra", "Bellmann", "Astar" to use the associated algorithm. Note that these methods are dynamic: the path is computed when needed. In contrarily, if the operand is another string, a static method will be used, i.e. all the shortest are previously computed.

15.0.130.4 Examples:

```
graphEpidemio <- graphEpidemio with_optimizer_type "static";
```

15.0.130.5 See also:

set_verbose,

15.0.131 `with_precision`

15.0.131.1 Possible use:

- point **with_precision** int —> point
- **with_precision** (point , int) —> point
- float **with_precision** int —> float
- **with_precision** (float , int) —> float
- geometry **with_precision** int —> geometry

- **with_precision** (geometry , int) —> geometry

15.0.131.2 Result:

Rounds off the ordinates of the left-hand point to the precision given by the value of right-hand operand Rounds off the value of left-hand operand to the precision given by the value of right-hand operand A geometry corresponding to the rounding of points of the operand considering a given precison.

15.0.131.3 Examples:

```
point var0 <- {12345.78943, 12345.78943, 12345.78943} with_precision 2 ; // var0 equals {12345.79, 12345
float var1 <- 12345.78943 with_precision 2; // var1 equals 12345.79
float var2 <- 123 with_precision 2; // var2 equals 123.00
geometry var3 <- self with_precision 2; // var3 equals the geometry resulting from the rounding of poin
```

15.0.131.4 See also:

round,

15.0.132 with_values

15.0.132.1 Possible use:

- predicate **with_values** map —> predicate
- **with_values** (predicate , map) —> predicate

15.0.132.2 Result:

change the parameters of the given predicate

15.0.132.3 Examples:

```
predicate with_values ["time"::10]
```

15.0.133 with_weights

15.0.133.1 Possible use:

- graph **with_weights** map —> graph
- **with_weights** (graph , map) —> graph
- graph **with_weights** list —> graph
- **with_weights** (graph , list) —> graph

15.0.133.2 Result:

returns the graph (left-hand operand) with weight given in the map (right-hand operand).

15.0.133.3 Comment:

this operand re-initializes the path finder

15.0.133.4 Special cases:

- if the right-hand operand is a list, affects the n elements of the list to the n first edges. Note that the ordering of edges may change overtime, which can create some problems...

- if the left-hand operand is a map, the map should contains pairs such as: vertex/edge::double

```
graph_from_edges (list(ant) as_map each::one_of (list(ant))) with_weights (list(ant) as_map each::each.
```

15.0.134 `without_holes`

15.0.134.1 Possible use:

- `without_holes` (geometry) —> geometry

15.0.134.2 Result:

A geometry corresponding to the operand geometry (geometry, agent, point) without its holes

15.0.134.3 Examples:

```
geometry var0 <- solid(self); // var0 equals the geometry corresponding to the geometry of the agent app
```

15.0.135 `writable`

15.0.135.1 Possible use:

- file **writable** bool —> file
- **writable** (file , bool) —> file

15.0.135.2 Result:

Marks the file as read-only or not, depending on the second boolean argument, and returns the first argument

15.0.135.3   Comment:

A file is created using its native flags. This operator can change them. Beware that this change is system-wide
(and not only restrained to GAMA): changing a file to read-only mode (e.g. "writable(f, false)")

15.0.135.4   Examples:

```
file var0 <- shape_file("../images/point_eau.shp") writable false; // var0 equals returns a file in rea
```

15.0.135.5   See also:

file,

15.0.136   xml_file

15.0.136.1   Possible use:

- **xml_file** (string) —> file

15.0.136.2   Result:

Constructs a file of type xml. Allowed extensions are limited to xml

---

15.0.137   xor

15.0.137.1   Possible use:

- bool **xor** bool —> bool
- **xor** (bool , bool) —> bool

15.0.137.2   Result:

a bool value, equal to the logical xor between the left-hand operand and the right-hand operand. False when
they are equal

15.0.137.3   Comment:

both operands are always casted to bool before applying the operator. Thus, an expression like 1 xor 0 is
accepted and returns true.

15.0.137.4   See also:

or, and, !,

15.0.138 `years_between`

15.0.138.1 Possible use:

- date **years_between** date —> int
- **years_between** (date , date) —> int

15.0.138.2 Result:

Provide the exact number of years between two dates. This number can be positive or negative (if the second operand is smaller than the first one)

15.0.138.3 Examples:

```
int var0 <- years_between(date('2000-01-01'), date('2010-01-01')); // var0 equals 10
```

  – catch,

- **user_command**

  – user_input,

- **user_first**

  – user_panel,

- **user_init**

  – user_panel,

- **user_last**

  – user_panel,

- **user_only**

  – user_panel,

- **user_panel**

  – user_command,

- **weighted_tasks**

  – task,

16.4   General syntax

A statement represents either a declaration or an imperative command. It consists in a keyword, followed by specific facets, some of them mandatory (in bold), some of them optional. One of the facet names can be omitted (the one denoted as omissible). It has to be the first one.

```
statement_keyword expression1 facet2: expression2 ... ;
or
statement_keyword facet1: expression1 facet2: expression2 ...;
```

If the statement encloses other statements, it is called a **sequence statement**, and its sub-statements (either sequence statements or single statements) are declared between curly brackets, as in:

```
statement_keyword1 expression1 facet2: expression2... { // a sequence statement
    statement_keyword2 expression1 facet2: expression2...;  // a single statement
    statement_keyword3 expression1 facet2: expression2...;
}
```

16.4.1 =

16.4.1.1 Facets

- `right` (float), (omissible) : the right part of the equation (it is mandatory that it can be evaluated as a float

- `left` (any type): the left part of the equation (it should be a variable or a call to the diff() or diff2() operators)

16.4.1.2 Definition

Allows to implement an equation in the form function(n, t) = expression. The left function is only here as a placeholder for enabling a simpler syntax and grabbing the variable as its left member.

16.4.1.3 Usages

- The syntax of the = statement is a bit different from the other statements. It has to be used as follows (in an equation):

```
float t; float S; float I; equation SI {     diff(S,t) = (- 0.3 * S * I / 100);     diff(I,t) = (0.3 * S
```

- See also: equation, solve,

16.4.1.4 Embedments

- The = statement is of type: **Single statement**
- The = statement can be embedded into: equation,
- The = statement embeds statements:

16.4.2 action

16.4.2.1 Facets

- `name` (an identifier), (omissible) : identifier of the action
- `index` (a datatype identifier): if the action returns a map, the type of its keys
- `of` (a datatype identifier): if the action returns a container, the type of its elements
- `type` (a datatype identifier): the action returned type
- `virtual` (boolean): whether the action is virtual (defined without a set of instructions) (false by default)

16.4.2.2 Definition

Allows to define in a species, model or experiment a new action that can be called elsewhere.

16.4.2.3   Usages

- The simplest syntax to define an action that does not take any parameter and does not return anything
  is: "'

action simple_action { // [set of statements] }

-   If the action needs some parameters, they can be specified betwee, braquets
    after the identifier of the action:

action action_parameters(int i, string s){ // [set of statements using i and s] }

* If the action returns any value, the returned type should be used instead of the "action" keyword. A :

int action_return_val(int i, string s){ // [set of statements using i and s] return i + i; }

-   If virtual: is true, then the action is abstract, which means that the
    action is defined without body. A species containing at least one abstract
    action is abstract. Agents of this species cannot be created. The common use
    of an abstract action is to define an action that can be used by all its
    sub-species, which should redefine all abstract actions and implements its
    body.

species parent_species { int virtual_action(int i, string s); } species children parent: parent_species { int
virtual_action(int i, string s) { return i + i; } }

* See also: [do](#do),

Embedments
* The `action` statement is of type: **Sequence of statements or action**
* The `action` statement can be embedded into: Species, Experiment, Model,
* The `action` statement embeds statements: [assert](#assert), [return](#return),

----

[//]: # (keyword|statement_add)
add
Facets

  * **`to`** (any type in [container, species, agent, geometry]): an expression that evaluates to a con
  * `item` (any type), (omissible) : any expression to add in the container
  * `all` (any type): Allows to either pass a container so as to add all its element, or 'true', if the
  * `at` (any type): position in the container of added element
  * `edge` (any type): a pair that will be added to a graph as an edge (if nodes do not exist, they are
  * `node` (any type): an expression that will be added to a graph as a node.
  * `vertex` (any type):
  * `weight` (float): An optional float value representing the weight to attach to this element in case

Definition

Allows to add, i.e. to insert, a new element in a container (a list, matrix, map, ...).Incorrect use: T

Usages

* The new element can be added either at the end of the container or at a particular position.

add expr to: expr_container; // Add at the end add expr at: expr to: expr_container; // Add at position expr

- Case of a list, the expression in the facet at: should be an integer.

list workingList <- []; add 0 at: 0 to: workingList ;//workingList equals [0]add 10 at: 0 to: workingList ;//workingList equals [10,0]add 20 at: 2 to: workingList ;//workingList equals [10,0,20]add 50 to: workingList;//workingList equals [10,0,20,50]add [60,70] all: true to: workingList;//workingList equals [10,0,20,50,60,70]

* Case of a map: As a map is basically a list of pairs key::value, we can also use the add statement on

map<string,string> workingMap <- []; add "val1" at: "x" to: workingMap;//workingMap equals ["x"::"val1"

- If the at facet is omitted, a pair expr_item::expr_item will be added to the
  map. An important exception is the case where the expr_item is a pair: in
  this case the pair is added.

add "val2" to: workingMap;//workingMap equals ["x"::"val1", "val2"::"val2"]add "5"::"val4" to: workingMap; //workingMap equals ["x"::"val1", "val2"::"val2", "5"::"val4"]

* Notice that, as the key should be unique, the addition of an item at an existing position (i.e. exist

add "val3" at: "x" to: workingMap;//workingMap equals ["x"::"val3", "val2"::"val2", "5"::"val4"

- On a map, the all facet will add all value of a container in the map (so as
  pair val_cont::val_cont)

add ["val4","val5"] all: true at: "x" to: workingMap;//workingMap equals ["x"::"val3", "val2"::"val2", "5"::"val4","val4"::"val4","val5"::"val5"]

* In case of a graph, we can use the facets `node`, `edge` and `weight` to add a node, an edge or weigh

graph g <- as_edge_graph([{1,5}::{12,45}]); add edge: {1,5}::{2,3} to: g;
list var <- g.vertices; // var equals [{1,5},{12,45},{2,3}] list var <- g.edges; // var equals [polyline({1.0,5.0}::{12.0,45.0}),polyline({1.0,5.0}::{2.0,3.0})]add node: {5,5} to: g;
list var <- g.vertices; // var equals [{1.0,5.0},{12.0,45.0},{2.0,3.0},{5.0,5.0}] list var <- g.edges; // var equals [polyline({1.0,5.0}::{12.0,45.0}),polyline({1.0,5.0}::{2.0,3.0})]

- Case of a matrix: this statement can not be used on matrix. Please refer to
  the statement put.

- See also: [put](#put), [remove](#remove),

Embedments

- The `add` statement is of type: **Single statement**

- The `add` statement can be embedded into: chart, Behavior, Sequence of statements or action, Layer,

- The `add` statement embeds statements:

agents

Facets

- `value` (container): the set of agents to display

- `name` (a label), (omissible) : Human readable title of the layer

- `aspect` (an identifier): the name of the aspect that should be used to display the species

- `fading` (boolean): Used in conjunction with 'trace:', allows to apply a fading effect to the previous traces. Default is false

- `focus` (agent): the agent on which the camera will be focused (it is dynamically computed)

- `position` (point): position of the upper-left corner of the layer. Note that if coordinates are in [0,1[, the position is relative to the size of the environment (e.g. {0.5,0.5} refers to the middle of the display) whereas it is absolute when coordinates are greater than 1 for x and y. The z-ordinate can only be defined between 0 and 1. The position can only be a 3D point {0.5, 0.5, 0.5}, the last coordinate specifying the elevation of the layer.

- `refresh` (boolean): (openGL only) specify whether the display of the species is refreshed. (true by default, useful in case of agents that do not move)

- `selectable` (boolean): Indicates whether the agents present on this layer are selectable by the user. Default is true

- `size` (point): extent of the layer in the screen from its position. Coordinates in [0,1[are treated as percentages of the total surface, while coordinates \> 1 are treated as absolute sizes in model units (i.e. considering the model occupies the entire view). Like in 'position', an elevation can be provided with the z coordinate, allowing to scale the layer in the 3 directions

- `trace` (any type in [boolean, int]): Allows to aggregate the visualization of agents at each timestep on the display. Default is false. If set to an int value, only the last n-th steps will be visualized. If set to true, no limit of timesteps is applied.

- `transparency` (float): the transparency rate of the agents (between 0 and 1, 1 means no transparency)

Definition

`agents` allows the modeler to display only the agents that fulfill a given
condition.

Usages

-   The general syntax is:

display my_display { agents layer_name value: expression [additional options]; }

* For instance, in a segregation model, `agents` will only display unhappy agents:

display Segregation { agents agentDisappear value: people as list where (each.is_happy = false) aspect:
with_group_color; }

-   See also: [display](#display), [chart](#chart), [event](#event),
    [graphics](#graphics), [display_grid](#display_grid), [image](#image),
    [overlay](#overlay), [display_population](#display_population),

Embedments

-   The `agents` statement is of type: **Layer**

-   The `agents` statement can be embedded into: display,

-   The `agents` statement embeds statements:

annealing

Facets

-   `name` (an identifier), (omissible) : The name of the method. For internal
    use only

-   `aggregation` (a label), takes values in: {min, max}: the agregation method

-   `maximize` (float): the value the algorithm tries to maximize

-   `minimize` (float): the value the algorithm tries to minimize

-   `nb_iter_cst_temp` (int): number of iterations per level of temperature

-   `temp_decrease` (float): temperature decrease coefficient

-   `temp_end` (float): final temperature

-   `temp_init` (float): initial temperature

Definition

This algorithm is an implementation of the Simulated Annealing algorithm. See

the wikipedia article and [batch161 the batch dedicated page].

Usages

-   As other batch methods, the basic syntax of the annealing statement uses
    `method annealing` instead of the expected `annealing name: id` :

method annealing [facet: value];

* For example:

method annealing temp_init: 100 temp_end: 1 temp_decrease: 0.5 nb_iter_cst_temp: 5 maximize:
food_gathered;

Embedments

-   The `annealing` statement is of type: **Batch method**

-   The `annealing` statement can be embedded into: Experiment,

-   The `annealing` statement embeds statements:

ask

Facets

-   `target` (any type in [container, agent]), (omissible) : an expression that
    evaluates to an agent or a list of agents

-   `as` (species): an expression that evaluates to a species

-   `parallel` (any type in [boolean, int]): (experimental) setting this facet
    to 'true' will allow 'ask' to use concurrency when traversing the targets;
    setting it to an integer will set the threshold under which they will be run
    sequentially (the default is initially 20, but can be fixed in the
    preferences). This facet is false by default.

Definition

Allows an agent, the sender agent (that can be the [Sections161\#global world
agent]), to ask another (or other) agent(s) to perform a set of statements. If
the value of the target facet is nil or empty, the statement is ignored.

Usages

-   Ask a set of receiver agents, stored in a container, to perform a block of
    statements. The block is evaluated in the context of the agents' species

ask ${receiver_agents} { ${cursor} }

* Ask one agent to perform a block of statements. The block is evaluated in the context of the agent's

ask ${one_agent} { ${cursor} }

- If the species of the receiver agent(s) cannot be determined, it is possible
  to force it using the `as` facet. An error is thrown if an agent is not a
  direct or undirect instance of this species

ask${receiver_agent(s)} as: ${a_species_expression} { ${cursor} }

* To ask a set of agents to do something only if they belong to a given species, the `of_species` opera

ask ${receiver_agents} of_species ${species_name} { ${cursor} }

- Any statement can be declared in the block statements. All the statements
  will be evaluated in the context of the receiver agent(s), as if they were
  defined in their species, which means that an expression like `self` will
  represent the receiver agent and not the sender. If the sender needs to
  refer to itself, some of its own attributes (or temporary variables) within
  the block statements, it has to use the keyword `myself`.

species animal { float energy <- rnd (1000) min: 0.0 { reflex when: energy > 500 { // executed when
the energy is above the given threshold list others <- (animal at_distance 5); // find all the neighboring
animals in a radius of 5 meters float shared_energy <- (energy - 500) / length (others); // compute the
amount of energy to share with each of them ask others { // no need to cast, since others has already been
filtered to only include animals if (energy < 500) { // refers to the energy of each animal in others energy
<- energy + myself.shared_energy; // increases the energy of each animal myself.energy <- myself.energy -
myself.shared_energy; // decreases the energy of the sender } } } }

Definition

Aspect statement is used to define a way to draw the current agent. Several aspects can be defined in on

Usages

* An example of use of the aspect statement:

species one_species { int a <- rnd(10); aspect aspect1 { if(a mod 2 = 0) { draw circle(a);} else {draw
square(a);} draw text: "a=" + a color: #black size: 5; } }

Embedments

-   The `aspect` statement is of type: **Behavior**

-   The `aspect` statement can be embedded into: Species, Model,

-   The `aspect` statement embeds statements: [draw](#draw),

assert

Facets

-   `value` (boolean), (omissible) : a boolean expression. If its evaluation is
    true, the assertion is successful. Otherwise, an error (or a warning) is
    raised.

-   `warning` (boolean): if set to true, makes the assertion emit a warning
    instead of an error

Definition

Allows to check if the evaluation of a given expression returns true. If not, an
error (or a warning) is raised. If the statement is used inside a test, the
error is not propagagated but invalidates the test (in case of a warning, it
partially invalidates it). Otherwise, it is normally propagated

Usages

-   Any boolean expression can be used

assert (2+2) = 4; assert self != nil; int t <- 0; assert is_error(3/t); (1 / 2) is float

* if the 'warn:' facet is set to true, the statement emits a warning (instead of an error) in case the

assert 'abc' is string warning: true

-   See also: [test](#test), [setup](#setup), [is_error](#is_error),
    [is_warning](#is_warning),

Embedments

-   The `assert` statement is of type: **Single statement**

-   The `assert` statement can be embedded into: test, action, Sequence of
    statements or action, Behavior, Sequence of statements or action,

-   The `assert` statement embeds statements:

benchmark

Facets

- `message` (any type), (omissible) : A message to display alongside the results. Should concisely describe the contents of the benchmark

- `repeat` (int): An int expression describing how many executions of the block must be handled. The output in this case will return the min, max and average durations

Definition

Displays in the console the duration in ms of the execution of the statements included in the block. It is possible to indicate, with the 'repeat' facet, how many times the sequence should be run

Usages

Embedments

- The `benchmark` statement is of type: **Sequence of statements or action**

- The `benchmark` statement can be embedded into: Behavior, Sequence of statements or action, Layer,

- The `benchmark` statement embeds statements:

break

Facets

Definition

`break` allows to interrupt the current sequence of statements.

Usages

Embedments

- The `break` statement is of type: **Single statement**

- The `break` statement can be embedded into: Sequence of statements or action,

- The `break` statement embeds statements:

camera

Facets

- `name` (string), (omissible) : The name of the camera

- `location` (point): The location of the camera in the world

- `look_at` (point): The location that the camera is looking

- `up_vector` (point): The up-vector of the camera.

Definition

`camera` allows the modeler to define a camera. The display will then be able to choose among the camera defined (either within this statement or globally in GAMA) in a dynamic way.

Usages

-   See also: [display](#display), [agents](#agents), [chart](#chart),
    [event](#event), [graphics](#graphics), [display_grid](#display_grid),
    [image](#image), [display_population](#display_population),

Embedments

-   The `camera` statement can be embedded into: display,

-   The `camera` statement embeds statements:

capture

Facets

-   `target` (any type in [agent, container]), (omissible) : an expression that
    is evaluated as an agent or a list of the agent to be captured

-   `as` (species): the species that the captured agent(s) will become, this is
    a micro-species of the calling agent's species

-   `returns` (a new identifier): a list of the newly captured agent(s)

Definition

Allows an agent to capture other agent(s) as its micro-agent(s).

Usages

-   The preliminary for an agent A to capture an agent B as its micro-agent is
    that the A's species must defined a micro-species which is a sub-species of
    B's species (cf. [Species161\#Nesting_species Nesting species]).

species A { … } species B { … species C parent: A { … } … }

* To capture all "A" agents as "C" agents, we can ask an "B" agent to execute the following statement:

capture list(B) as: C;

-   Deprecated writing:

capture target: list (B) as: C;

* See also: [release](#release),

Embedments

conscious_contagion

Facets

-   `emotion_created` (546706): the emotion that will be created with the
    contagion

-   `emotion_detected` (546706): the emotion that will start the contagion

-   `name` (an identifier), (omissible) : the identifier of the unconscious
    contagion

-   `charisma` (float): The charisma value of the perceived agent (between 0 and
    1)

-   `decay` (float): The decay value of the emotion added to the agent

-   `intensity` (float): The intensity value of the emotion added to the agent

-   `receptivity` (float): The receptivity value of the current agent (between 0
    and 1)

-   `threshold` (float): The threshold value to make the contagion

-   `when` (boolean): A boolean value to get the emotion only with a certain
    condition

Definition

enables to directly add an emotion of a perceived specie if the perceived agent
ges a patricular emotion.

Usages

* `returns` (a new identifier): a new temporary variable name containing the list of created agents (a
* `with` (map): an expression that evaluates to a map, for each pair the key is a species attribute an

Definition

Allows an agent to create `number` agents of species `species`, to create agents of species `species` f

Usages

* Its simple syntax to create `an_int` agents of species `a_species` is:

create a_species number: an_int; create species_of(self) number: 5 returns: list5Agents; 5

- In GAML modelers can create agents of species `a_species` (with two
  attributes `type` and `nature` with types corresponding to the types of the
  shapefile attributes) from a shapefile `the_shapefile\` while reading
  attributes 'TYPE_OCC' and 'NATURE' of the shapefile. One agent will be
  created by object contained in the shapefile:

create a_species from: the_shapefile with: [type:: read('TYPE_OCC'), nature::read('NATURE')];

* In order to create agents from a .csv file, facet `header` can be used to specified whether we can use

create toto from: "toto.csv" header: true with:[att1::read("NAME"), att2::read("TYPE")]; or create toto
from: "toto.csv" with:[att1::read(0), att2::read(1)]; //with read(int), the index of the column

- Similarly to the creation from shapefile, modelers can create agents from a
  set of geometries. In this case, one agent per geometry will be created
  (with the geometry as shape)

create species_of(self) from: [square(4),circle(4)]; // 2 agents have been created, with shapes respectively
square(4) and circle(4)

* Created agents are initialized following the rules of their species. If one wants to refer to them af

create species (self) number: rnd (4) returns: children; ask children { // … }

- If one wants to specify a special initialization sequence for the agents
  created, create provides the same possibilities as ask. This extended syntax
  is:

create a_species number: an_int { statements }

* The same rules as in ask apply. The only difference is that, for the agents created, the assignments

create species(self) number: rnd (4) returns: children { set location <- myself.location + {rnd (2), rnd (2)};
// tells the children to be initially located close to me set parent <- myself; // tells the children that their
parent is me (provided the variable parent is declared in this species) }

- Desprecated uses:

// Simple syntax create species: a_species number: an_int;

* If `number` equals 0 or species is not a species, the statement is ignored.

Embedments
* The `create` statement is of type: **Sequence of statements or action**
* The `create` statement can be embedded into: Behavior, Sequence of statements or action,

display

Facets

-   `name` (a label), (omissible) : the identifier of the display

-   `ambient_light` (any type in [int, rgb]): Allows to define the value of the
    ambient light either using an int (ambient_light:(125)) or a rgb color
    ((ambient_light:rgb(255,255,255)). default is rgb(127,127,127,255)

-   `autosave` (any type in [boolean, point]): Allows to save this display on
    disk. A value of true/false will save it at a resolution of 500x500. A point
    can be passed to personalize these dimensions

- `background` (rgb): Allows to fill the background of the display with a specific color

- `camera_interaction` (boolean): If false, the user will not be able to modify the position and the orientation of the camera, and neither using the ROI. Default is true.

- `camera_lens` (int): Allows to define the lens of the camera

- `camera_look_pos` (point): Allows to define the direction of the camera

- `camera_pos` (any type in [point, agent]): Allows to define the position of the camera

- `camera_up_vector` (point): Allows to define the orientation of the camera

- `diffuse_light` (any type in [int, rgb]): Allows to define the value of the diffuse light either using an int (diffuse_light:(125)) or a rgb color ((diffuse_light:rgb(255,255,255)). default is (127,127,127,255)

- `diffuse_light_pos` (point): Allows to define the position of the diffuse light either using an point (diffuse_light_pos:{x,y,z}). default is {world.shape.width/2,world.shape.height/2,world.shape.width`*`2}

- `draw_diffuse_light` (boolean): Allows to show/hide a representation of the lights. Default is false.

- `draw_env` (boolean): Allows to enable/disable the drawing of the world shape and the ordinate axes. Default can be configured in Preferences

- `focus` (geometry): the geometry (or agent) on which the display will (dynamically) focus

- `fullscreen` (any type in [boolean, int]): Indicates, when using a boolean value, whether or not the display should cover the whole screen (default is false). If an integer is passed, specifies also the screen to use: 0 for the primary monitor, 1 for the secondary one, and so on and so forth. If the monitor is not available, the first one is used

- `keystone` (container): Set the position of the 4 corners of your screen ([topLeft,topRight,botLeft,botRight]), in (x,y) coordinate (the (0,0) position is the top left corner, while the (1,1) position is the bottom right corner). The default value is : [{0,0},{1,0},{0,1},{1,1}]

- `light` (boolean): Allows to enable/disable the light. Default is true

- `orthographic_projection` (boolean): Allows to enable/disable the orthographic projection. Default can be configured in Preferences

- `parent` (an identifier): Declares that this display inherits its layers and attributes from the parent display named as the argument. Expects the identifier of the parent display or a string if the name of the parent contains spaces

- `refresh` (boolean): Indicates the condition under which this output should be refreshed (default is true)

- `refresh_every` (int): Allows to refresh the display every n time steps (default is 1)

- `rotate` (float): Set the angle for the rotation around the Z axis

- `scale` (any type in [boolean, float]): Allows to display a scale bar in the overlay. Accepts true/false or an unit name

- `show_fps` (boolean): Allows to enable/disable the drawing of the number of frames per second

- `synchronized` (boolean): Indicates whether the display should be directly synchronized with the simulation

- `toolbar` (boolean): Indicates whether the top toolbar of the display view should be initially visible or not

- `type` (a label): Allows to use either Java2D (for planar models) or OpenGL (for 3D models) as the rendering subsystem

- `use_shader` (boolean): Under construction...

- `virtual` (boolean): Declaring a display as virtual makes it invisible on screen, and only usable for display inheritance

- `z_fighting` (boolean): Allows to alleviate a problem where agents at the same z would overlap each other in random ways

Definition

A display refers to a independent and mobile part of the interface that can display species, images, texts or charts.

Usages

- The general syntax is:

display my_display [additional options] { … }

* Each display can include different layers (like in a GIS).

display gridWithElevationTriangulated type: opengl ambient_light: 100 { grid cell elevation: true triangulation: true; species people aspect: base; }

Embedments

- The `display` statement is of type: **Output**

- The `display` statement can be embedded into: output, permanent,

- The `display` statement embeds statements: [agents](#agents),
  [camera](#camera), [chart](#chart), [display_grid](#display_grid),
  [display_population](#display_population), [event](#event),
  [graphics](#graphics), [image](#image), [light](#light),
  [overlay](#overlay),

display_grid

Facets

- `species` (species), (omissible) : the species of the agents in the grid

- `dem` (matrix):

- `draw_as_dem` (boolean):

- `elevation` (any type in [matrix, float, int, boolean]): Allows to specify
  the elevation of each cell, if any. Can be a matrix of float (provided it
  has the same size than the grid), an int or float variable of the grid
  species, or simply true (in which case, the variable called 'grid_value' is
  used to compute the elevation of each cell)

- `grayscale` (boolean): if true, givse a grey value to each polygon depending
  on its elevation (false by default)

- `lines` (rgb): the color to draw lines (borders of cells)

- `position` (point): position of the upper-left corner of the layer. Note
  that if coordinates are in [0,1[, the position is relative to the size of
  the environment (e.g. {0.5,0.5} refers to the middle of the display) whereas
  it is absolute when coordinates are greater than 1 for x and y. The
  z-ordinate can only be defined between 0 and 1. The position can only be a
  3D point {0.5, 0.5, 0.5}, the last coordinate specifying the elevation of
  the layer.

- `refresh` (boolean): (openGL only) specify whether the display of the
  species is refreshed. (true by default, usefull in case of agents that do
  not move)

- `selectable` (boolean): Indicates whether the agents present on this layer
  are selectable by the user. Default is true

- `size` (point): extent of the layer in the screen from its position.
  Coordinates in [0,1[are treated as percentages of the total surface, while
  coordinates \> 1 are treated as absolute sizes in model units (i.e.
  considering the model occupies the entire view). Like in 'position', an
  elevation can be provided with the z coordinate, allowing to scale the layer
  in the 3 directions

- `text` (boolean): specify whether the attribute used to compute the
  elevation is displayed on each cells (false by default)

- `texture` (any type in [boolean, file]): Either file containing the texture

image to be applied on the grid or, if true, the use of the image composed
by the colors of the cells. If false, no texture is applied

- `transparency` (float): the transparency rate of the agents (between 0 and
  1, 1 means no transparency)

- `triangulation` (boolean): specifies whther the cells will be triangulated:
  if it is false, they will be displayed as horizontal squares at a given
  elevation, whereas if it is true, cells will be triangulated and linked to
  neighbors in order to have a continuous surface (false by default)

Definition

`display_grid` is used using the `grid` keyword. It allows the modeler to
display in an optimized way all cell agents of a grid (i.e. all agents of a
species having a grid topology).

Usages

- The general syntax is:

display my_display { grid ant_grid lines: #black position: { 0.5, 0 } size: {0.5,0.5}; }

* To display a grid as a DEM:

display my_display { grid cell texture: texture_file text: false triangulation: true elevation: true; }

- See also: [display](#display), [agents](#agents), [chart](#chart),
  [event](#event), [graphics](#graphics), [image](#image),
  [overlay](#overlay), [display_population](#display_population),

Embedments

- The `display_grid` statement is of type: **Layer**

- The `display_grid` statement can be embedded into: display,

- The `display_grid` statement embeds statements:

display_population

Facets

- `species` (species), (omissible) : the species to be displayed

- `aspect` (an identifier): the name of the aspect that should be used to
  display the species

- `fading` (boolean): Used in conjunction with 'trace:', allows to apply a
  fading effect to the previous traces. Default is false

- `position` (point): position of the upper-left corner of the layer. Note
  that if coordinates are in [0,1[, the position is relative to the size of

the environment (e.g. {0.5,0.5} refers to the middle of the display) whereas
it is absolute when coordinates are greater than 1 for x and y. The
z-ordinate can only be defined between 0 and 1. The position can only be a
3D point {0.5, 0.5, 0.5}, the last coordinate specifying the elevation of
the layer.

-   `refresh` (boolean): (openGL only) specify whether the display of the
    species is refreshed. (true by default, usefull in case of agents that do
    not move)

-   `selectable` (boolean): Indicates whether the agents present on this layer
    are selectable by the user. Default is true

-   `size` (point): extent of the layer in the screen from its position.
    Coordinates in [0,1[are treated as percentages of the total surface, while
    coordinates \> 1 are treated as absolute sizes in model units (i.e.
    considering the model occupies the entire view). Like in 'position', an
    elevation can be provided with the z coordinate, allowing to scale the layer
    in the 3 directions

-   `trace` (any type in [boolean, int]): Allows to aggregate the visualization
    of agents at each timestep on the display. Default is false. If set to an
    int value, only the last n-th steps will be visualized. If set to true, no
    limit of timesteps is applied.

-   `transparency` (float): the transparency rate of the agents (between 0 and
    1, 1 means no transparency)

Definition

The `display_population` statement is used using the `species keyword`. It
allows modeler to display all the agent of a given species in the current
display. In particular, modeler can choose the aspect used to display them.

Usages

-   The general syntax is:

display my_display { species species_name [additional options]; }

* Species can be superposed on the same plan (be careful with the order, the last one will be above all

display my_display { species agent1 aspect: base; species agent2 aspect: base; species agent3 aspect: base;
}

-   Each species layer can be placed at a different z value using the opengl
    display. position:{0,0,0} means the layer will be placed on the ground and
    position:{0,0,1} means it will be placed at an height equal to the maximum
    size of the environment.

display my_display type: opengl{ species agent1 aspect: base ; species agent2 aspect: base position:{0,0,0.5};
species agent3 aspect: base position:{0,0,1}; }

* See also: [display](#display), [agents](#agents), [chart](#chart), [event](#event), [graphics](#graph

Embedments
* The `display_population` statement is of type: **Layer**
* The `display_population` statement can be embedded into: display, display_population,
* The `display_population` statement embeds statements: [display_population](#display_population),

----

[//]: # (keyword|statement_do)
do
Facets

  * **`action`** (an identifier), (omissible) : the name of an action or a primitive
  * `internal_function` (any type):
  * `returns` (a new identifier): create a new variable and assign to it the result of the action
  * `with` (map): a map expression containing the parameters of the action

Definition

Allows the agent to execute an action or a primitive. For a list of primitives available in every spec

Usages

* The simple syntax (when the action does not expect any argument and the result is not to be kept) is:

do name_of_action_or_primitive;

-    In case the action expects one or more arguments to be passed, they are
     defined by using facets (enclosed tags or a map are now deprecated):

do name_of_action_or_primitive arg1: expression1 arg2: expression2;

* In case the result of the action needs to be made available to the agent, the action can be called wi

type_returned_by_action result <- self name_of_action_or_primitive [];

-    In case of an action expecting arguments and returning a value, the
     following syntax is used:

type_returned_by_action result <- self name_of_action_or_primitive [arg1::expression1, arg2::expression2];

* Deprecated uses: following uses of the `do` statement (still accepted) are now deprecated:

// Simple syntax: do action: name_of_action_or_primitive; // In case the result of the action needs
to be made available to the agent, the **returns** keyword can be defined; the result will then be
referred to by the temporary variable declared in this attribute: do name_of_action_or_primitive
returns: result; do name_of_action_or_primitive arg1:   expression1 arg2:   expression2 returns:
result;   type_returned_by_action   result   <-   name_of_action_or_primitive(self,   [arg1::expression1,
arg2::expression2]); // In case the result of the action needs to be made available to the agent let result
<- name_of_action_or_primitive(self, []); // In case the action expects one or more arguments to

be passed, they can also be defined by using enclosed `arg` statements, or the `with` facet with a map of parameters: do name_of_action_or_primitive with: [arg1::expression1, arg2::expression2]; or do name_of_action_or_primitive { arg arg1 value: expression1; arg arg2 value: expression2; … }

Embedments

-   The `do` statement is of type: **Single statement**

-   The `do` statement can be embedded into: chart, Behavior, Sequence of statements or action,

-   The `do` statement embeds statements:

draw

Facets

-   `geometry` (any type), (omissible) : any type of data (it can be geometry, image, text)

-   `anchor` (point): the anchor point of the location with respect to the envelope of the text to draw, can take one of the following values: \#center, \#top_left, \#left_center, \#bottom_left, \#bottom_center, \#bottom_right, \#right_center, \#top_right, \#top_center

-   `at` (point): location where the shape/text/icon is drawn

-   `begin_arrow` (any type in [int, float]): the size of the arrow, located at the beginning of the drawn geometry

-   `bitmap` (boolean): Whether to render the text in 3D or not

-   `border` (any type in [rgb, boolean]): if used with a color, represents the color of the geometry border. If set to false, expresses that no border should be drawn. If not set, the borders will be drawn using the color of the geometry.

-   `color` (any type in [rgb, container]): the color to use to display the object. In case of images, will try to colorize it. You can also pass a list of colors : in that case, each color will be matched to its corresponding vertex.

-   `depth` (float): (only if the display type is opengl) Add an artificial depth to the geometry previously defined (a line becomes a plan, a circle becomes a cylinder, a square becomes a cube, a polygon becomes a polyhedron with height equal to the depth value). Note: This only works if the geometry is not a point

-   `empty` (boolean): a condition specifying whether the geometry is empty or full

-   `end_arrow` (any type in [int, float]): the size of the arrow, located at the end of the drawn geometry

-   `font` (any type in [19, string]): the font used to draw the text, if any.
    Applying this facet to geometries or images has no effect. You can construct
    here your font with the operator "font". ex : font:font("Helvetica", 20 ,
    \#plain)

-   `material` (25): Set a particular material to the object (only if you are in
    the "use_shader" mode).

-   `perspective` (boolean): Whether to render the text in perspective or facing
    the user. Default is true.

-   `rotate` (any type in [float, int, pair]): orientation of the
    shape/text/icon; can be either an int/float (angle) or a pair float::point
    (angle::rotation axis). The rotation axis, when expressed as an angle, is by
    defaut {0,0,1}

-   `rounded` (boolean): specify whether the geometry have to be rounded (e.g.
    for squares)

-   `size` (any type in [float, point]): size of the object to draw, expressed
    as a bounding box (width, height, depth). If expressed as a float,
    represents the size in the three directions.

-   `texture` (any type in [string, list, file]): the texture(s) that should be
    applied to the geometry. Either a path to a file or a list of paths

-   `width` (float): The line width to use for drawing this object

Definition

`draw` is used in an aspect block to express how agents of the species will be
drawn. It is evaluated each time the agent has to be drawn. It can also be used
in the graphics block.

Usages

-   Any kind of geometry as any location can be drawn when displaying an agent
    (independently of his shape)

aspect geometryAspect { draw circle(1.0) empty: !hasFood color: #orange ; }

* Image or text can also be drawn

aspect arrowAspect { draw "Current state="+state at: location + {-3,1.5} color: #white font: font('Default',
12, #bold) ; draw file(ant_shape_full) rotate: heading at: location size: 5 }

-   Arrows can be drawn with any kind of geometry, using begin_arrow and
    end_arrow facets, combined with the empty: facet to specify whether it is
    plain or empty

aspect arrowAspect { draw line([{20, 20}, {40, 40}]) color: #black begin_arrow:5; draw line([{10, 10},{20,
50}, {40, 70}]) color: #green end_arrow: 2 begin_arrow: 2 empty: true; draw square(10) at: {80,20} color:

#purple begin_arrow: 2 empty: true; }

Embedments

equation

Facets

-    `name` (an identifier), (omissible) : the equation identifier

-    `params` (list): the list of parameters used in predefined equation systems

-    `simultaneously` (list): a list of species containing a system of equations
     (all systems will be solved simultaneously)

-    `type` (an identifier), takes values in: {SI, SIS, SIR, SIRS, SEIR, LV}: the
     choice of one among classical models (SI, SIS, SIR, SIRS, SEIR, LV)

-    `vars` (list): the list of variables used in predefined equation systems

Definition

The equation statement is used to create an equation system from several single
equations.

Usages

-    The basic syntax to define an equation system is:

float t; float S; float I; equation SI { diff(S,t) = (- 0.3 * S * I / 100); diff(I,t) = (0.3 * S * I / 100); }

* If the type: facet is used, a predefined equation system is defined using variables vars: and paramet

equation eqSI type: SI vars: [S,I,t] params: [N,beta]; equation eqSIS type: SIS vars: [S,I,t] params:
[N,beta,gamma]; equation eqSIR type:SIR vars:[S,I,R,t] params:[N,beta,gamma]; equation eqSIRS type:

SIRS vars: [S,I,R,t] params: [N,beta,gamma,omega,mu]; equation eqSEIR type: SEIR vars: [S,E,I,R,t] params: [N,beta,gamma,sigma,mu]; equation eqLV type: LV vars: [x,y,t] params: [alpha,beta,delta,gamma] ;

- If the simultaneously: facet is used, system of all the agents will be
  solved simultaneously.

  * `aggregation` (a label), takes values in: {min, max}: The aggregation method to use (either min or
  * `maximize` (float): the value the algorithm tries to maximize
  * `minimize` (float): the value the algorithm tries to minimize

Definition

This is the standard batch method. The exhaustive mode is defined by default when there is no method el

Usages

* As other batch methods, the basic syntax of the exhaustive statement uses `method exhaustive` instead
method exhaustive [facet: value];

-    For example:

method exhaustive maximize: food_gathered;

Embedments
* The `exhaustive` statement is of type: **Batch method**

* The `exhaustive` statement can be embedded into: Experiment,
* The `exhaustive` statement embeds statements:

[//]: # (keyword|statement_exit)
exit
Facets

Definition

In an FSM architecture, `exit` introduces a sequence of statements to execute right before exiting the s

Usages

* In the following example, at the state it leaves the state s_init, he will display the message 'EXIT

state s_init initial: true {   write state;   transition to: s1 when: (cycle > 2) {

-    See also: [enter](#enter), [state](#state), [transition](#transition),

Embedments

-    The `exit` statement is of type: **Sequence of statements or action**

-    The `exit` statement can be embedded into: state,

-    The `exit` statement embeds statements:

experiment

Facets

-    `name` (a label), (omissible) : identifier of the experiment

-    `title` (a label):

-    `type` (a label), takes values in: {batch, memorize, gui, test, headless}:
     the type of the experiment (either 'gui' or 'batch'

-    `autorun` (boolean): whether this experiment should be run automatically
     when launched (false by default)

-    `control` (an identifier):

-    `frequency` (int): the execution frequence of the experiment (default value:
     1). If frequency: 10, the experiment is executed only each 10 steps.

-    `keep_seed` (boolean):

-    `keep_simulations` (boolean): In the case of a batch experiment, specifies

  whether or not the simulations should be kept in memory for further analysis
  or immediately discarded with only their fitness kept in memory

- `parallel` (any type in [boolean, int]): When set to true, use multiple
  threads to run its simulations. Setting it to n will set the numbers of
  threads to use

- `parent` (an identifier): the parent experiment (in case of inheritance
  between experiments)

- `repeat` (int): In the case of a batch experiment, expresses hom many times
  the simulations must be repeated

- `schedules` (container): A container of agents (a species, a dynamic list,
  or a combination of species and containers) , which represents which agents
  will be actually scheduled when the population is scheduled for execution.
  For instance, 'species a schedules: (10 among a)' will result in a
  population that schedules only 10 of its own agents every cycle. 'species b
  schedules: []' will prevent the agents of 'b' to be scheduled. Note that the
  scope of agents covered here can be larger than the population, which allows
  to build complex scheduling controls; for instance, defining 'global
  schedules: [] {...} species b schedules: []; species c schedules: b + world;
  ' allows to simulate a model where the agents of b are scheduled first,
  followed by the world, without even having to create an instance of c.

- `skills` (list):

- `until` (boolean): In the case of a batch experiment, an expression that
  will be evaluated to know when a simulation should be terminated

- `virtual` (boolean): whether the experiment is virtual (cannot be
  instantiated, but only used as a parent, false by default)

Definition

Declaration of a particular type of agent that can manage simulations

Usages

Embedments

- The `experiment` statement is of type: **Experiment**

- The `experiment` statement can be embedded into: Model,

- The `experiment` statement embeds statements:

focus

Facets

- `agent_cause` (agent): the agentCause value of the created belief (can be
  nil

- `belief` (546704): The predicate to focus on the beliefs of the other agent

- `desire` (546704): The predicate to focus on the desires of the other agent

- `emotion` (546706): The emotion to focus on the emotions of the other agent

- `expression` (any type): an expression that will be the value kept in the belief

- `id` (string): the identifier of the focus

- `ideal` (546704): The predicate to focus on the ideals of the other agent

- `is_uncertain` (boolean): a boolean to indicate if the mental state created is an uncertainty

- `lifetime` (int): the lifetime value of the created belief

- `strength` (any type in [float, int]): The priority of the created predicate

- `truth` (boolean): the truth value of the created belief

- `uncertainty` (546704): The predicate to focus on the uncertainties of the other agent

- `var` (any type in [any type, list, container]): the variable of the perceived agent you want to add to your beliefs

- `when` (boolean): A boolean value to focus only with a certain condition

Definition

enables to directly add a belief from the variable of a perceived specie.

Usages

- Other examples of use:

focus var:speed */where speed is a variable from a species that is being perceived/*

Embedments
* The `focus` statement is of type: **Single statement**

    statements or action, Layer,

-   The `focus_on` statement embeds statements:

genetic

Facets

-   `name` (an identifier), (omissible) : The name of this method. For internal
    use only

-   `aggregation` (a label), takes values in: {min, max}: the agregation method

-   `crossover_prob` (float): crossover probability between two individual
    solutions

-   `improve_sol` (boolean): if true, use a hill climbing algorithm to improve
    the solutions at each generation

-   `max_gen` (int): number of generations

-   `maximize` (float): the value the algorithm tries to maximize

-   `minimize` (float): the value the algorithm tries to minimize

-   `mutation_prob` (float): mutation probability for an individual solution

-   `nb_prelim_gen` (int): number of random populations used to build the
    initial population

-   `pop_dim` (int): size of the population (number of individual solutions)

-   `stochastic_sel` (boolean): if true, use a stochastic selection algorithm
    (roulette) rather a determistic one (keep the best solutions)

Definition

This is a simple implementation of Genetic Algorithms (GA). See the wikipedia
article and [batch161 the batch dedicated page]. The principle of the GA is to

search an optimal solution by applying evolution operators on an initial
population of solutions. There are three types of evolution operators:
crossover, mutation and selection. Different techniques can be applied for this
selection. Most of them are based on the solution quality (fitness).

Usages

-   As other batch methods, the basic syntax of the `genetic` statement uses
    `method genetic` instead of the expected `genetic name: id` :

method genetic [facet: value];

* For example:

method genetic maximize: food_gathered pop_dim: 5 crossover_prob: 0.7 mutation_prob: 0.1
nb_prelim_gen: 1 max_gen: 20;

Embedments

-   The `genetic` statement is of type: **Batch method**

-   The `genetic` statement can be embedded into: Experiment,

-   The `genetic` statement embeds statements:

graphics

Facets

-   `name` (a label), (omissible) : the human readable title of the graphics

-   `fading` (boolean): Used in conjunction with 'trace:', allows to apply a
    fading effect to the previous traces. Default is false

-   `position` (point): position of the upper-left corner of the layer. Note
    that if coordinates are in [0,1[, the position is relative to the size of
    the environment (e.g. {0.5,0.5} refers to the middle of the display) whereas
    it is absolute when coordinates are greater than 1 for x and y. The
    z-ordinate can only be defined between 0 and 1. The position can only be a
    3D point {0.5, 0.5, 0.5}, the last coordinate specifying the elevation of
    the layer.

-   `refresh` (boolean): (openGL only) specify whether the display of the
    species is refreshed. (true by default, usefull in case of agents that do
    not move)

-   `size` (point): extent of the layer in the screen from its position.
    Coordinates in [0,1[are treated as percentages of the total surface, while
    coordinates \> 1 are treated as absolute sizes in model units (i.e.
    considering the model occupies the entire view). Like in 'position', an
    elevation can be provided with the z coordinate, allowing to scale the layer
    in the 3 directions

- `trace` (any type in [boolean, int]): Allows to aggregate the visualization
  at each timestep on the display. Default is false. If set to an int value,
  only the last n-th steps will be visualized. If set to true, no limit of
  timesteps is applied.

- `transparency` (float): the transparency rate of the agents (between 0 and
  1, 1 means no transparency)

Definition

`graphics` allows the modeler to freely draw shapes/geometries/texts without
having to define a species. It works exactly like a species [Aspect161 aspect]:
the draw statement can be used in the same way.

Usages

-   The general syntax is:

display my_display { graphics "my new layer" { draw circle(5) at: {10,10} color: #red; draw "test" at:
{10,10} size: 20 color: #black; } }

* See also: [display](#display), [agents](#agents), [chart](#chart), [event](#event), [graphics](#graph

Embedments
* The `graphics` statement is of type: **Layer**
* The `graphics` statement can be embedded into: display,
* The `graphics` statement embeds statements:

[//]: # (keyword|statement_highlight)
highlight
Facets

  * **`value`** (agent), (omissible) : The agent to hightlight
  * `color` (rgb): An optional color to highlight the agent. Note that this color will become the defau

Definition

Allows to highlight the agent passed in parameter in all available displays, optionaly setting a color.

Usages

* Highlighting an agent

highlight my_species(0) color: #blue;

Embedments

-   The `highlight` statement is of type: **Single statement**

-   The `highlight` statement can be embedded into: Behavior, Sequence of
    statements or action, Layer,

- The `highlight` statement embeds statements:

hill_climbing

Facets

- `name` (an identifier), (omissible) : The name of the method. For internal use only

- `aggregation` (a label), takes values in: {min, max}: the agregation method

- `iter_max` (int): number of iterations

- `maximize` (float): the value the algorithm tries to maximize

- `minimize` (float): the value the algorithm tries to minimize

Definition

This algorithm is an implementation of the Hill Climbing algorithm. See the wikipedia article and [batch161 the batch dedicated page].

Usages

- As other batch methods, the basic syntax of the `hill_climbing` statement uses `method hill_climbing` instead of the expected `hill_climbing name: id` :

method hill_climbing [facet: value];

* For example:

method hill_climbing iter_max: 50 maximize : food_gathered;

Embedments

- The `hill_climbing` statement is of type: **Batch method**

- The `hill_climbing` statement can be embedded into: Experiment,

- The `hill_climbing` statement embeds statements:

if

Facets

- `condition` (boolean), (omissible) : A boolean expression: the condition that is evaluated.

Definition

Allows the agent to execute a sequence of statements if and only if the

condition evaluates to true.

Usages

-   The generic syntax is:

if bool_expr { statements }

* Optionally, the statements to execute when the condition evaluates to false can be defined in a follo

if bool_expr { statements } else { statements } string valTrue <- ""; if true { valTrue <- "true"; } else
{ valTrue <- "false"; } //valTrue equals "true"string valFalse <- ""; if false { valFalse <- "true"; } else {
valFalse <- "false"; } //valFalse equals "false"

-   ifs and elses can be imbricated as needed. For instance:

if bool_expr { statements } else if bool_expr2 { statements } else { statements }

Embedments
* The `if` statement is of type: **Sequence of statements or action**
* The `if` statement can be embedded into: Behavior, Sequence of statements or action, Layer,
* The `if` statement embeds statements: [else](#else),

[//]: # (keyword|statement_image)
image
Facets

  * `name` (any type in [string, file]), (omissible) : Human readable title of the image layer
  * `color` (rgb): in the case of a shapefile, this the color used to fill in geometries of the shapefi
  * `file` (any type in [string, file]): the name/path of the image (in the case of a raster image)
  * `gis` (any type in [file, string]): the name/path of the shape file (to display a shapefile as backg
  * `position` (point): position of the upper-left corner of the layer. Note that if coordinates are in
  * `refresh` (boolean): (openGL only) specify whether the image display is refreshed or not. (false by
  * `size` (point): extent of the layer in the screen from its position. Coordinates in [0,1[are treate
  * `transparency` (float): the transparency rate of the agents (between 0 and 1, 1 means no transparenc

Definition

`image` allows modeler to display an image (e.g. as background of a simulation).

Usages

* The general syntax is:

display my_display { image layer_name file: image_file [additional options]; }

-   For instance, in the case of a bitmap image

display my_display { image background file:"../images/my_backgound.jpg"; }

* Or in the case of a shapefile:

display my_display { image testGIS gis: "../includes/building.shp" color: rgb('blue'); }

- It is also possible to superpose images on different layers in the same way
  as for species using opengl display:

display my_display { image image1 file:"../images/image1.jpg"; image image2 file:"../images/image2.jpg";
image image3 file:"../images/image3.jpg" position: {0,0,0.5}; }

* See also: [display](#display), [agents](#agents), [chart](#chart), [event](#event), [graphics](#graph:

Embedments
* The `image` statement is of type: **Layer**
* The `image` statement can be embedded into: display,
* The `image` statement embeds statements:

[//]: # (keyword|statement_inspect)
inspect
Facets

  * **`name`** (any type), (omissible) : the identifier of the inspector
  * `attributes` (list): the list of attributes to inspect. A list that can contain strings or pair<str:
  * `refresh` (boolean): Indicates the condition under which this output should be refreshed (default i:
  * `refresh_every` (int): Allows to refresh the inspector every n time steps (default is 1)
  * `type` (an identifier), takes values in: {agent, table}: the way to inspect agents: in a table, or :
  * `value` (any type): the set of agents to inspect, could be a species, a list of agents or an agent

Definition

`inspect` (and `browse`) statements allows modeler to inspect a set of agents, in a table with agents a:

Usages

* An example of syntax is:

inspect "my_inspector" value: ant attributes: ["name", "location"];

Embedments

- The `inspect` statement is of type: **Output**

- The `inspect` statement can be embedded into: output, permanent, Behavior,
  Sequence of statements or action,

- The `inspect` statement embeds statements:

law

Facets

-   `name` (an identifier), (omissible) : The name of the law

-   `all` (boolean): add an obligation for each belief

-   `belief` (546704): The mandatory belief

-   `beliefs` (list): The mandatory beliefs

-   `lifetime` (int): the lifetime value of the mental state created

-   `new_obligation` (546704): The predicate that will be added as an obligation

-   `new_obligations` (list): The list of predicates that will be added as
    obligations

-   `parallel` (any type in [boolean, int]): setting this facet to 'true' will
    allow 'perceive' to use concurrency with a parallel_bdi architecture;
    setting it to an integer will set the threshold under which they will be run
    sequentially (the default is initially 20, but can be fixed in the
    preferences). This facet is true by default.

-   `strength` (any type in [float, int]): The stregth of the mental state
    created

-   `threshold` (float): Threshold linked to the obedience value.

-   `when` (boolean):

Definition

enables to add a desire or a belief or to remove a belief, a desire or an
intention if the agent gets the belief or/and desire or/and condition mentioned.

Usages

-   Other examples of use:

rule belief: new_predicate("test") when: flip(0.5) new_desire: new_predicate("test")

Embedments
* The `law` statement is of type: **Single statement**
* The `law` statement can be embedded into: Species, Model,
* The `law` statement embeds statements:

[//]: # (keyword|statement_layout)
layout
Facets

  * `value` (any type), (omissible) : Either #none, to indicate that no layout will be imposed, or one

* `tabs` (boolean): Whether the displays should show their tab or not
* `toolbars` (boolean): Whether the displays should show their toolbar or not

Definition

Represents the layout of the display views of simulations and experiments

Usages

* For instance, this layout statement will allow to split the screen occupied by displays in four equal

layout horizontal([vertical([0::5000,1::5000])::5000,vertical([2::5000,3::5000])::5000]) tabs: false;

Embedments

-   The `layout` statement is of type: **Output**

-   The `layout` statement can be embedded into: Experiment,

-   The `layout` statement embeds statements:

let

Facets

-   `name` (a new identifier), (omissible) : The name of the variable declared

-   `index` (a datatype identifier): The type of the index if this declaration
    concerns a container

-   `of` (a datatype identifier): The type of the contents if this declaration
    concerns a container

-   `type` (a datatype identifier): The type of the variable

-   `value` (any type): The value assigned to this variable

Definition

Allows to declare a temporary variable of the specified type and to initialize
it with a value

Usages

Embedments

-   The `let` statement is of type: **Single statement**

-   The `let` statement can be embedded into: Behavior, Sequence of statements
    or action, Layer,

-   The `let` statement embeds statements:

light

Facets

-   `id` (int), (omissible) : a number from 1 to 7 to specify which light we are
    using

-   `active` (boolean): a boolean expression telling if you want this light to
    be switch on or not. (default value : true)

-   `color` (any type in [int, rgb]): an int / rgb / rgba value to specify the
    color and the intensity of the light. (default value : (127,127,127,255)).

-   `direction` (point): the direction of the light (only for direction and spot
    light). (default value : {0.5,0.5,-1})

-   `draw_light` (boolean): draw or not the light. (default value : false).

-   `linear_attenuation` (float): the linear attenuation of the positionnal
    light. (default value : 0)

-   `position` (point): the position of the light (only for point and spot
    light). (default value : {0,0,1})

-   `quadratic_attenuation` (float): the linear attenuation of the positionnal
    light. (default value : 0)

-   `spot_angle` (float): the angle of the spot light in degree (only for spot
    light). (default value : 45)

-   `type` (a label): the type of light to create. A value among {point,
    direction, spot}. (default value : direction)

-   `update` (boolean): specify if the light has to be updated. (default value :
    true).

Definition

`light` allows to define diffusion lights in your 3D display.

Usages

-   The general syntax is:

light 1 type:point position:{20,20,20} color:255, linear_attenuation:0.01 quadratic_attenuation:0.0001
draw_light:true update:false light 2 type:spot position:{20,20,20} direction:{0,0,-1} color:255 spot_angle:25
linear_attenuation:0.01 quadratic_attenuation:0.0001 draw_light:true update:false light 3 type:point
direction:{1,1,-1} color:255 draw_light:true update:false

* See also: [display](#display),

Embedments
* The `light` statement is of type: **Layer**
* The `light` statement can be embedded into: display,

* The `light` statement embeds statements:

[//]: # (keyword|statement_loop)
loop
Facets

  * `name` (a new identifier), (omissible) : a temporary variable name
  * `from` (int): an int expression
  * `over` (any type in [container, point]): a list, point, matrix or map expression
  * `step` (int): an int expression
  * `times` (int): an int expression
  * `to` (int): an int expression
  * `while` (boolean): a boolean expression

Definition

Allows the agent to perform the same set of statements either a fixed number of times, or while a condi

Usages

* The basic syntax for repeating a fixed number of times a set of statements is:

loop times: an_int_expression { // statements }

-   The basic syntax for repeating a set of statements while a condition holds
    is:

loop while: a_bool_expression { // statements }

* The basic syntax for repeating a set of statements by progressing over a container of a point is:

loop a_temp_var over: a_collection_expression { // statements }

-   The basic syntax for repeating a set of statements while an index iterates
    over a range of values with a fixed step of 1 is:

loop a_temp_var from: int_expression_1 to: int_expression_2 { // statements }

* The incrementation step of the index can also be chosen:

loop a_temp_var from: int_expression_1 to: int_expression_2 step: int_expression3 { // statements }

-   In these latter three cases, the name facet designates the name of a
    temporary variable, whose scope is the loop, and that takes, in turn, the
    value of each of the element of the list (or each value in the interval).
    For example, in the first instance of the "loop over" syntax :

int a <- 0; loop i over: [10, 20, 30] { a <- a + i; } // a now equals 60

* The second (quite common) case of the loop syntax allows one to use an interval of integers. The from

list the_list <-list (species_of (self)); loop i from: 0 to: length (the_list) - 1 { ask the_list at i { // … } }
// every agent of the list is asked to do something

Embedments

-    The `loop` statement is of type: **Sequence of statements or action**

-    The `loop` statement can be embedded into: Behavior, Sequence of statements
     or action, Layer,

-    The `loop` statement embeds statements:

match

Facets

-    `value` (any type), (omissible) : The value or values this statement tries
     to match

Definition

In a switch...match structure, the value of each match block is compared to the
value in the switch. If they match, the embedded statement set is executed.
Three kinds of match can be used

Usages

-    match block is executed if the switch value is equals to the value of the
     match:

switch 3 { match 1 {write "Match 1"; } match 3 {write "Match 2"; } }

* match_between block is executed if the switch value is in the interval given in value of the match_bet

switch 3 { match_between [1,2] {write "Match OK between [1,2]"; } match_between [2,5] {write "Match
OK between [2,5]"; } }

-    match_one block is executed if the switch value is equals to one of the
     values of the match_one:

switch 3 { match_one [0,1,2] {write "Match OK with one of [0,1,2]"; } match_between [2,3,4,5] {write
"Match OK with one of [2,3,4,5]"; } }

* See also: [switch](#switch), [default](#default),

Embedments
* The `match` statement is of type: **Sequence of statements or action**
* The `match` statement can be embedded into: switch,
* The `match` statement embeds statements:

[//]: # (keyword|statement_migrate)
migrate
Facets

  * **`source`** (any type in [agent, species, container, an identifier]), (omissible) : can be an agent
  * **`target`** (species): target species/population that source agent(s) migrate to.
  * `returns` (a new identifier): the list of returned agents in a new local variable

Definition

This command permits agents to migrate from one population/species to another population/species and st

Usages

* It can be used in a 3-levels model, in case where individual agents can be captured into group meso a

migrate ball_in_group target: ball_in_cloud;

-   See also: [capture](#capture), [release](#release),

Embedments

-   The `migrate` statement is of type: **Sequence of statements or action**

-   The `migrate` statement can be embedded into: Behavior, Sequence of
    statements or action,

-   The `migrate` statement embeds statements:

monitor

Facets

-   `name` (a label), (omissible) : identifier of the monitor

-   `value` (any type): expression that will be evaluated to be displayed in the
    monitor

-   `color` (rgb): Indicates the (possibly dynamic) color of this output
    (default is a light gray)

-   `refresh` (boolean): Indicates the condition under which this output should
    be refreshed (default is true)

-   `refresh_every` (int): Allows to refresh the monitor every n time steps
    (default is 1)

Definition

A monitor allows to follow the value of an arbitrary expression in GAML.

Usages

-   An example of use is:

monitor "nb preys" value: length(prey as list) refresh_every: 5;

Embedments
* The `monitor` statement is of type: **Output**
* The `monitor` statement can be embedded into: output, permanent,
* The `monitor` statement embeds statements:

[//]: # (keyword|statement_norm)
norm
Facets

  * `name` (an identifier), (omissible) :
  * `finished_when` (boolean):
  * `instantaneous` (boolean):
  * `intention` (546704):
  * `lifetime` (int):
  * `obligation` (546704):
  * `priority` (float):
  * `threshold` (float):
  * `when` (boolean):

Embedments
* The `norm` statement is of type: **Behavior**
* The `norm` statement can be embedded into: Species, Model,
* The `norm` statement embeds statements:

[//]: # (keyword|statement_output)
output
Facets

Definition

`output` blocks define how to visualize a simulation (with one or more display blocks that define separa

Usages

* Its basic syntax is:

experiment exp_name type: gui { // [inputs] output { // [display, file, inspect, layout or monitor statements]
} }

-   See also: [display](#display), [monitor](#monitor), [inspect](#inspect),
    [output_file](#output_file), [layout](#layout),

Embedments

- The `output` statement is of type: **Output**

- The `output` statement can be embedded into: Model, Experiment,

- The `output` statement embeds statements: [display](#display),
  [inspect](#inspect), [monitor](#monitor), [output_file](#output_file),

output_file

Facets

- `name` (an identifier), (omissible) : The name of the file where you want to
  export the data

- `data` (string): The data you want to export

- `footer` (string): Define a footer for your export file

- `header` (string): Define a header for your export file

- `refresh` (boolean): Indicates the condition under which this file should be
  saved (default is true)

- `refresh_every` (int): Allows to save the file every n time steps (default
  is 1)

- `rewrite` (boolean): Rewrite or not the existing file

- `type` (an identifier), takes values in: {csv, text, xml}: The type of your
  output data

Definition

Represents an output that writes the result of expressions into a file

Usages

Embedments

- The `output_file` statement is of type: **Output**

- The `output_file` statement can be embedded into: output, permanent,

- The `output_file` statement embeds statements:

overlay

Facets

- `background` (rgb): the background color of the overlay displayed inside the

    view (the bottom overlay remains black)

-   `border` (rgb): Color to apply to the border of the rectangular shape of the
    overlay. Nil by default

-   `center` (any type): an expression that will be evaluated and displayed in
    the center section of the bottom overlay

-   `color` (any type in [list, rgb]): the color(s) used to display the
    expressions given in the 'left', 'center' and 'right' facets

-   `left` (any type): an expression that will be evaluated and displayed in the
    left section of the bottom overlay

-   `position` (point): position of the upper-left corner of the layer. Note
    that if coordinates are in [0,1[, the position is relative to the size of
    the environment (e.g. {0.5,0.5} refers to the middle of the display) whereas
    it is absolute when coordinates are greater than 1 for x and y. The
    z-ordinate can only be defined between 0 and 1. The position can only be a
    3D point {0.5, 0.5, 0.5}, the last coordinate specifying the elevation of
    the layer.

-   `right` (any type): an expression that will be evaluated and displayed in
    the right section of the bottom overlay

-   `rounded` (boolean): Whether or not the rectangular shape of the overlay
    should be rounded. True by default

-   `size` (point): extent of the layer in the view from its position.
    Coordinates in [0,1[are treated as percentages of the total surface of the
    view, while coordinates \> 1 are treated as absolute sizes in model units
    (i.e. considering the model occupies the entire view). Unlike 'position', no
    elevation can be provided with the z coordinate

-   `transparency` (float): the transparency rate of the overlay (between 0 and
    1, 1 means no transparency) when it is displayed inside the view. The bottom
    overlay will remain at 0.75

Definition

`overlay` allows the modeler to display a line to the already existing bottom
overlay, where the results of 'left', 'center' and 'right' facets, when they are
defined, are displayed with the corresponding color if defined.

Usages

-   To display information in the bottom overlay, the syntax is:

overlay "Cycle:" + (cycle) center: "Duration:" + total_duration + "ms" right: "Model time:" +
as_date(time,"") color: [#yellow, #orange, #yellow];

* See also: [display](#display), [agents](#agents), [chart](#chart), [event](#event), [graphics](#graph

Embedments
* The `overlay` statement is of type: **Layer**
* The `overlay` statement can be embedded into: display,
* The `overlay` statement embeds statements:

[//]: # (keyword|statement_parameter)
parameter
Facets

  * **`var`** (an identifier): the name of the variable (that should be declared in the global)
  * `name` (a label), (omissible) : The message displayed in the interface
  * `among` (list): the list of possible values
  * `category` (a label): a category label, used to group parameters in the interface
  * `disables` (list): a list of global variables whose parameter editors will be disabled when this pa
  * `enables` (list): a list of global variables whose parameter editors will be enabled when this param
  * `init` (any type): the init value
  * `max` (any type): the maximum value
  * `min` (any type): the minimum value
  * `on_change` (any type): Provides a block of statements that will be executed whenever the value of
  * `slider` (boolean): Whether or not to display a slider for entering an int or float value. Default
  * `step` (float): the increment step (mainly used in batch mode to express the variation step between
  * `type` (a datatype identifier): the variable type
  * `unit` (a label): the variable unit

Definition

The parameter statement specifies which global attributes (i) will change through the successive simul

Usages

* In gui experiment, the general syntax is the following:

parameter title var: global_var category: cat;

-   In batch experiment, the two following syntaxes can be used to describe the
    possible values of a parameter:

parameter 'Value of toto:' var: toto among: [1, 3, 7, 15, 100]; parameter 'Value of titi:' var: titi min: 1 max:
100 step: 2;

Embedments
* The `parameter` statement is of type: **Parameter**
* The `parameter` statement can be embedded into: Experiment,
* The `parameter` statement embeds statements:

[//]: # (keyword|statement_perceive)
perceive
Facets

  * **`target`** (any type in [container, agent]): the list of the agent you want to perceive
  * `name` (an identifier), (omissible) : the name of the perception
  * `as` (species): an expression that evaluates to a species
  * `emotion` (546706): The emotion needed to do the perception
  * `in` (any type in [float, geometry]): a float or a geometry. If it is a float, it's a radius of a d
  * `parallel` (any type in [boolean, int]): setting this facet to 'true' will allow 'perceive' to use
  * `threshold` (float): Threshold linked to the emotion.
  * `when` (boolean): a boolean to tell when does the perceive is active

Definition

Allow the agent, with a bdi architecture, to perceive others agents

Usages

* the basic syntax to perceive agents inside a circle of perception

perceive name_of-perception target: the_agents_you_want_to_perceive in: a_distance when:
a_certain_condition { Here you are in the context of the perceived agents.   To refer to the agent
who does the perception, use myself. If you want to make an action (such as adding a belief for example),
use ask myself{ do the_action} }

Embedments

-   The `perceive` statement is of type: **Sequence of statements or action**

-   The `perceive` statement can be embedded into: Species, Model,

-   The `perceive` statement embeds statements:

permanent

Facets

-   `layout` (any type), (omissible) : Either \#none, to indicate that no layout
    will be imposed, or one of the four possible predefined layouts: \#stack,
    \#split, \#horizontal or \#vertical. This layout will be applied to both
    experiment and simulation display views. In addition, it is possible to
    define a custom layout using the horizontal() and vertical() operators

-   `tabs` (boolean): Whether the displays should show their tab or not

-   `toolbars` (boolean): Whether the displays should show their toolbar or not

Definition

Represents the outputs of the experiment itself. In a batch experiment, the
permanent section allows to define an output block that will NOT be
re-initialized at the beginning of each simulation but will be filled at the end
of each simulation.

Usages

- For instance, this permanent section will allow to display for each
  simulation the end value of the food_gathered variable:

permanent { display Ants background: rgb('white') refresh_every: 1 { chart "Food Gathered" type: series
{ data "Food" value: food_gathered; } } }

Embedments
* The `permanent` statement is of type: **Output**
* The `permanent` statement can be embedded into: Experiment,
* The `permanent` statement embeds statements: [display](#display), [inspect](#inspect), [monitor](#m

put
Facets

  * **`in`** (any type in [container, species, agent, geometry]): an expression that evaluates to a con
  * `item` (any type), (omissible) : any expression
  * `all` (any type): any expression
  * `at` (any type): any expression
  * `edge` (any type): Indicates that the item to put should be considered as an edge of the receiving g
  * `key` (any type): any expression
  * `weight` (float): an expression that evaluates to a float

Definition

Allows the agent to replace a value in a container at a given position (in a list or a map) or for a gi

Usages

* The allowed parameters configurations are the following ones:

put expr at: expr in: expr_container; put all: expr in: expr_container;

```
-    In the case of a list, the position should an integer in the bound of the
     list. The facet all: is used to replace all the elements of the list by the
     given value.
```

list putList <- [1,2,3,4,5]; //putList equals [1,2,3,4,5]put -10 at: 1 in: putList;//putList equals [1,-10,3,4,5]put 10 all: true in: putList;//putList equals [10,10,10,10,10]

```
* In the case of a matrix, the position should be a point in the bound of the matrix. The facet all: is
```

matrix putMatrix <- matrix([[0,1],[2,3]]); //putMatrix equals matrix([[0,1],[2,3]])put -10 at: {1,1} in: putMatrix;//putMatrix equals matrix([[0,1],[2,-10]])put 10 all: true in: putMatrix;//putMatrix equals matrix([[10,10],[10,10]])

```
-    In the case of a map, the position should be one of the key values of the
     map. Notice that if the given key value does not exist in the map, the given
     pair key::value will be added to the map. The facet all is used to replace
     the value of all the pairs of the map.
```

map putMap <- ["x"::4,"y"::7]; //putMap equals ["x"::4,"y"::7]put -10 key: "y" in: putMap;//putMap equals ["x"::4,"y"::-10]put -20 key: "z" in: putMap;//putMap equals ["x"::4,"y"::-10, "z"::-20]put -30 all: true in: putMap;//putMap equals ["x"::-30,"y"::-30, "z"::-30]

```

[//]: # (keyword|statement_reactive_tabu)
### reactive_tabu
#### Facets

  * **`name`** (an identifier), (omissible) :
  * `aggregation` (a label), takes values in: {min, max}: the agregation method
  * `cycle_size_max` (int): minimal size of the considered cycles
  * `cycle_size_min` (int): maximal size of the considered cycles
  * `iter_max` (int): number of iterations
  * `maximize` (float): the value the algorithm tries to maximize
  * `minimize` (float): the value the algorithm tries to minimize
  * `nb_tests_wthout_col_max` (int): number of movements without collision before shortening the tabu l:
  * `tabu_list_size_init` (int): initial size of the tabu list
  * `tabu_list_size_max` (int): maximal size of the tabu list
  * `tabu_list_size_min` (int): minimal size of the tabu list

#### Definition

This algorithm is a simple implementation of the Reactive Tabu Search algorithm ((Battiti et al., 1993)
```

Usages

* As other batch methods, the basic syntax of the reactive_tabu statement uses `method reactive_tabu` i

method reactive_tabu [facet: value];

- For example:

method reactive_tabu iter_max: 50 tabu_list_size_init: 5 tabu_list_size_min: 2 tabu_list_size_max:
10 nb_tests_wthout_col_max: 20 cycle_size_min: 2 cycle_size_max: 20 maximize: food_gathered;

Embedments
* The `reactive_tabu` statement is of type: **Batch method**
* The `reactive_tabu` statement can be embedded into: Experiment,
* The `reactive_tabu` statement embeds statements:

[//]: # (keyword|statement_reflex)
reflex
Facets

  * `name` (an identifier), (omissible) : the identifier of the reflex
  * `when` (boolean): an expression that evaluates a boolean, the condition to fulfill in order to exec

Definition

Reflexes are sequences of statements that can be executed by the agent. Reflexes prefixed by the 'refle

Usages

* Example:

reflex my_reflex when: flip (0.5){ //Only executed when flip returns true write "Executing the unconditional
reflex"; }

Embedments

-   The `reflex` statement is of type: **Behavior**

-   The `reflex` statement can be embedded into: Species, Experiment, Model,

-   The `reflex` statement embeds statements:

release

Facets

-   `target` (any type in [agent, list, 27]), (omissible) : an expression that
    is evaluated as an agent/a list of the agents to be released or an agent
    saved as a map

-   `as` (species): an expression that is evaluated as a species in which the
    micro-agent will be released

-   `in` (agent): an expression that is evaluated as an agent that will be the
    macro-agent in which micro-agent will be released, i.e. their new host

-   `returns` (a new identifier): a new variable containing a list of the newly
    released agent(s)

Definition

Allows an agent to release its micro-agent(s). The preliminary for an agent to
release its micro-agents is that species of these micro-agents are sub-species
of other species (cf. [Species161\#Nesting_species Nesting species]). The
released agents won't be micro-agents of the calling agent anymore. Being
released from a macro-agent, the micro-agents will change their species and host
(macro-agent).

Usages

-   We consider the following species. Agents of "C" species can be released
    from a "B" agent to become agents of "A" species. Agents of "D" species
    cannot be released from the "A" agent because species "D" has no parent
    species.

species A { ... } species B { ... species C parent: A { ... } species D { ... } ... }

* To release all "C" agents from a "B" agent, agent "C" has to execute the following statement. The "C"

release list(C);

-   The modeler can specify the new host and the new species of the released
    agents:

release list (C) as: new_species in: new host;

* See also: [capture](#capture),

Embedments
* The `release` statement is of type: **Sequence of statements or action**
* The `release` statement can be embedded into: Behavior, Sequence of statements or action,
* The `release` statement embeds statements:

[//]: # (keyword|statement_remove)
remove
Facets

  * **`from`** (any type in [container, species, agent, geometry]): an expression that evaluates to a c
  * `item` (any type), (omissible) : any expression to remove from the container

* `all` (any type): an expression that evaluates to a container. If it is true and if the value a list
* `edge` (any type): Indicates that the item to remove should be considered as an edge of the receivir
* `index` (any type): any expression, the key at which to remove the element from the container
* `key` (any type): any expression, the key at which to remove the element from the container
* `node` (any type): Indicates that the item to remove should be considered as a node of the receiving
* `vertex` (any type):

Definition

Allows the agent to remove an element from a container (a list, matrix, map...).

Usages

* This statement should be used in the following ways, depending on the kind of container used and the

remove expr from: expr_container; remove index: expr from: expr_container; remove key: expr from: expr_container; remove all: expr from: expr_container;

-   In the case of list, the facet `item:` is used to remove the first occurence
    of a given expression, whereas `all` is used to remove all the occurrences
    of the given expression.

list removeList <- [3,2,1,2,3]; remove 2 from: removeList;//removeList equals [3,1,2,3]remove 3 all: true from: removeList;//removeList equals [1,2]remove index: 1 from: removeList;//removeList equals [1]

* In the case of map, the facet `key:` is used to remove the pair identified by the given key.

map<string,int> removeMap <- ["x"::5, "y"::7, "z"::7]; remove key: "x" from: removeMap;//removeMap equals ["y"::7, "z"::7]remove 7 all: true from: removeMap;//removeMap equals map([])

-   In addition, a map a be managed as a list with pair key as index. Given
    that, facets item:, all: and index: can be used in the same way:

map removeMapList <- ["x"::5, "y"::7, "z"::7, "t"::5]; remove 7 from: removeMapList;//removeMapList equals ["x"::5, "z"::7, "t"::5]remove [5,7] all: true from: removeMapList;//removeMapList equals ["t"::5]remove index: "t" from: removeMapList;//removeMapList equals map([]

* In the case of a graph, both edges and nodes can be removes using node: and edge facets. If a node is

graph removeGraph <- as_edge_graph([{1,2}::{3,4},{3,4}::{5,6}]); remove node: {1,2} from: removeGraph; remove node(1,2) from: removeGraph;
list var <- removeGraph.vertices; // var equals [{3,4},{5,6}] list var <- removeGraph.edges; // var equals [polyline({3,4}::{5,6})]remove edge: {3,4}::{5,6} from: removeGraph; remove edge({3,4},{5,6}) from: removeGraph;
list var <- removeGraph.vertices; // var equals [{3,4},{5,6}] list var <- removeGraph.edges; // var equals [

-   In the case of an agent or a shape, `remove` allows to remove an attribute
    from the attributes map of the receiver. However, for agents, it will only
    remove attributes that have been added dynamically, not the ones defined in
    the species or in its built-in parent.

global { init { create speciesRemove; speciesRemove sR <- speciesRemove(0); // sR.a now equals 100 remove
key:"a" from: sR; // sR.a now equals nil } } species speciesRemove { int a <- 100; }

* This statement can not be used on *matrix*.
* See also: [add](#add), [put](#put),

Embedments
* The `remove` statement is of type: **Single statement**
* The `remove` statement can be embedded into: chart, Behavior, Sequence of statements or action, Layer
* The `remove` statement embeds statements:

[//]: # (keyword|statement_return)
return
Facets

  * `value` (any type), (omissible) : an expression that is returned

Definition

Allows to immediately stop and tell which value to return from the evaluation of the surrounding action

Usages

* Example:

string foo { return "foo"; } reflex { string foo_result <- foo(); // foos_result is now equals to "foo" }

-    In the specific case one wants an agent to ask another agent to execute a
     statement with a return, it can be done similarly to:

// In Species A: string foo_different { return "foo_not_same"; } /// …. // In Species B: reflex writing {
string temp <- some_agent_A.foo_different []; // temp is now equals to "foo_not_same" }

Embedments
* The `return` statement is of type: **Single statement**
* The `return` statement can be embedded into: action, Behavior, Sequence of statements or action,
* The `return` statement embeds statements:

[//]: # (keyword|statement_rule)
rule
Facets

  * `name` (an identifier), (omissible) : The name of the rule
  * `all` (boolean): add a desire for each belief
  * `belief` (546704): The mandatory belief
  * `beliefs` (list): The mandatory beliefs

* `desire` (546704): The mandatory desire
* `desires` (list): The mandatory desires
* `emotion` (546706): The mandatory emotion
* `emotions` (list): The mandatory emotions
* `ideal` (546704): The mandatory ideal
* `ideals` (list): The mandatory ideals
* `lifetime` (int): the lifetime value of the mental state created
* `new_belief` (546704): The belief that will be added
* `new_beliefs` (list): The belief that will be added
* `new_desire` (546704): The desire that will be added
* `new_desires` (list): The desire that will be added
* `new_emotion` (546706): The emotion that will be added
* `new_emotions` (list): The emotion that will be added
* `new_ideal` (546704): The ideal that will be added
* `new_ideals` (list): The ideals that will be added
* `new_uncertainties` (list): The uncertainty that will be added
* `new_uncertainty` (546704): The uncertainty that will be added
* `obligation` (546704): The mandatory obligation
* `obligations` (list): The mandatory obligations
* `parallel` (any type in [boolean, int]): setting this facet to 'true' will allow 'perceive' to use
* `remove_belief` (546704): The belief that will be removed
* `remove_beliefs` (list): The belief that will be removed
* `remove_desire` (546704): The desire that will be removed
* `remove_desires` (list): The desire that will be removed
* `remove_emotion` (546706): The emotion that will be removed
* `remove_emotions` (list): The emotion that will be removed
* `remove_ideal` (546704): The ideal that will be removed
* `remove_ideals` (list): The ideals that will be removed
* `remove_intention` (546704): The intention that will be removed
* `remove_obligation` (546704): The obligation that will be removed
* `remove_obligations` (list): The obligation that will be removed
* `remove_uncertainties` (list): The uncertainty that will be removed
* `remove_uncertainty` (546704): The uncertainty that will be removed
* `strength` (any type in [float, int]): The stregth of the mental state created
* `threshold` (float): Threshold linked to the emotion.
* `uncertainties` (list): The mandatory uncertainties
* `uncertainty` (546704): The mandatory uncertainty
* `when` (boolean):

Definition

enables to add a desire or a belief or to remove a belief, a desire or an intention if the agent gets th

save

Facets

-   `data` (any type), (omissible) : any expression, that will be saved in the
    file

-   `attributes` (map): Allows to specify the attributes of a shape file where
    agents are saved. The keys of the map are the names of the attributes that

will be present in the file, the values are whatever expressions neeeded to
define their value

- `crs` (any type): the name of the projection, e.g. crs:"EPSG:4326" or its
  EPSG id, e.g. crs:4326. Here a list of the CRS codes (and EPSG id):
  http://spatialreference.org

- `header` (boolean): an expression that evaluates to a boolean, specifying
  whether the save will write a header if the file does not exist

- `rewrite` (boolean): an expression that evaluates to a boolean, specifying
  whether the save will ecrase the file or append data at the end of it.
  Default is true

- `to` (string): an expression that evaluates to an string, the path to the
  file, or directly to a file

- `type` (an identifier), takes values in: {shp, text, csv, asc, geotiff,
  image}: an expression that evaluates to an string, the type of the output
  file (it can be only "shp", "asc", "geotiff", "image", "text" or "csv")

- `with` (map): Allows to define the attributes of a shape file. Keys of the
  map are the attributes of agents to save, values are the names of attributes
  in the shape file

Definition

Allows to save data in a file. The type of file can be "shp", "asc", "geotiff",
"text" or "csv".

Usages

- Its simple syntax is:

save data to: output_file type: a_type_file;

* To save data in a text file:

save (string(cycle) + "->" + name + ":" + location) to: "save_data.txt" type: "text";

- To save the values of some attributes of the current agent in csv file:

save [name, location, host] to: "save_data.csv" type: "csv";

* To save the values of all attributes of all the agents of a species into a csv (with optional attribu-

save species_of(self) to: "save_csvfile.csv" type: "csv" header: false;

- To save the geometries of all the agents of a species into a shapefile (with
  optional attributes):

save species_of(self) to: "save_shapefile.shp" type: "shp" with: [name::"nameAgent", location::"locationAgent"]

crs: "EPSG:4326";

* To save the grid_value attributes of all the cells of a grid into an ESRI ASCII Raster file:
save grid to: "save_grid.asc" type: "asc";

-    To save the grid_value attributes of all the cells of a grid into geotiff:
save grid to: "save_grid.tif" type: "geotiff";

* To save the grid_value attributes of all the cells of a grid into png (with a worldfile):
save grid to: "save_grid.png" type: "image";

-    The save statement can be use in an init block, a reflex, an action or in a
     user command. Do not use it in experiments.

Embedments

-    The `save` statement is of type: **Single statement**

-    The `save` statement can be embedded into: Behavior, Sequence of statements
     or action,

-    The `save` statement embeds statements:

set

Facets

-    `name` (any type), (omissible) : the name of an existing variable or
     attribute to be modified

-    `value` (any type): the value to affect to the variable or attribute

Definition

Allows to assign a value to the variable or attribute specified

Usages

Embedments

    or action,

-   The `solve` statement embeds statements:

species

Facets

-   `name` (an identifier), (omissible) : the identifier of the species

-   `cell_height` (float): (grid only), the height of the cells of the grid

-   `cell_width` (float): (grid only), the width of the cells of the grid

-   `compile` (boolean):

-   `control` (22): defines the architecture of the species (e.g. fsm...)

-   `edge_species` (species): In the case of a species defining a graph topology
    for its instances (nodes of the graph), specifies the species to use for
    representing the edges

-   `file` (file): (grid only), a bitmap file that will be loaded at runtime so
    that the value of each pixel can be assigned to the attribute 'grid_value'

-   `files` (list): (grid only), a list of bitmap file that will be loaded at
    runtime so that the value of each pixel of each file can be assigned to the
    attribute 'bands'

-   `frequency` (int): The execution frequency of the species (default value:
    1). For instance, if frequency is set to 10, the population of agents will

be executed only every 10 cycles.

- `height` (int): (grid only), the height of the grid (in terms of agent number)

- `horizontal_orientation` (boolean): (hexagonal grid only),(true by default). Allows use a hexagonal grid with a horizontal or vertical orientation.

- `mirrors` (any type in [list, species]): The species this species is mirroring. The population of this current species will be dependent of that of the species mirrored (i.e. agents creation and death are entirely taken in charge by GAMA with respect to the demographics of the species mirrored). In addition, this species is provided with an attribute called 'target', which allows each agent to know which agent of the mirrored species it is representing.

- `neighbors` (int): (grid only), the chosen neighborhood (4, 6 or 8)

- `neighbours` (int): (grid only), the chosen neighborhood (4, 6 or 8)

- `optimizer` (string): (grid only),("A*" by default). Allows to specify the algorithm for the shortest path computation ("BF", "Dijkstra", "A*" or "JPS*"

- `parallel` (any type in [boolean, int]): (experimental) setting this facet to 'true' will allow this species to use concurrency when scheduling its agents; setting it to an integer will set the threshold under which they will be run sequentially (the default is initially 20, but can be fixed in the preferences). This facet has a default set in the preferences (Under Performances \> Concurrency)

- `parent` (species): the parent class (inheritance)

- `schedules` (container): A container of agents (a species, a dynamic list, or a combination of species and containers) , which represents which agents will be actually scheduled when the population is scheduled for execution. For instance, 'species a schedules: (10 among a)' will result in a population that schedules only 10 of its own agents every cycle. 'species b schedules: []' will prevent the agents of 'b' to be scheduled. Note that the scope of agents covered here can be larger than the population, which allows to build complex scheduling controls; for instance, defining 'global schedules: [] {...} species b schedules: []; species c schedules: b + world; ' allows to simulate a model where the agents of b are scheduled first, followed by the world, without even having to create an instance of c.

- `skills` (list): The list of skills that will be made available to the instances of this species. Each new skill provides attributes and actions that will be added to the ones defined in this species

- `topology` (topology): The topology of the population of agents defined by this species. In case of nested species, it can for example be the shape of the macro-agent. In case of grid or graph species, the topology is automatically computed and cannot be redefined

- `torus` (boolean): is the topology toric (defaut: false). Needs to be defined on the global species.

- `use_individual_shapes` (boolean): (grid only),(true by default). Allows to specify whether or not the agents of the grid will have distinct geometries. If set to false, they will all have simpler proxy geometries

- `use_neighbors_cache` (boolean): (grid only),(true by default). Allows to turn on or off the use of the neighbors cache used for grids. Note that if a diffusion of variable occurs, GAMA will emit a warning and automatically switch to a caching version

- `use_regular_agents` (boolean): (grid only),(true by default). Allows to specify if the agents of the grid are regular agents (like those of any other species) or minimal ones (which can't have sub-populations, can't inherit from a regular species, etc.)

- `virtual` (boolean): whether the species is virtual (cannot be instantiated, but only used as a parent) (false by default)

- `width` (int): (grid only), the width of the grid (in terms of agent number)

Definition

The species statement allows modelers to define new species in the model. `global` and `grid` are speciel cases of species: `global` being the definition of the global agent (which has automatically one instance, world) and `grid` being a species with a grid topology.

Usages

- Here is an example of a species definition with a FSM architecture and the additional skill moving:

species ant skills: [moving] control: fsm {

* In the case of a species aiming at mirroring another one:

species node_agent mirrors: list(bug) parent: graph_node edge_species: edge_agent {

- The definition of the single grid of a model will automatically create gridwidth x gridheight agents:

grid ant_grid width: gridwidth height: gridheight file: grid_file neighbors: 8 use_regular_agents: false {

* Using a file to initialize the grid can replace width/height facets:

grid ant_grid file: grid_file neighbors: 8 use_regular_agents: false {

Embedments

- The `start_simulation` statement embeds statements:

state

Facets

- `name` (an identifier), (omissible) : the identifier of the state

- `final` (boolean): specifies whether the state is a final one (i.e. there is no transition from this state to another state) (default value= false)

- `initial` (boolean): specifies whether the state is the initial one (default value = false)

Definition

A state, like a reflex, can contains several statements that can be executed at each time step by the agent.

Usages

- Here is an exemple integrating 2 states and the statements in the FSM architecture:

state s_init initial: true {   enter { write "Enter in" + state; }   write "Enter in" + s

* See also: [enter](#enter), [exit](#exit), [transition](#transition),

* Outputting a message
```

status ('This is my status' + self) color: #yellow;

```
#### Embedments
```

- The `status` statement is of type: **Single statement**

- The `status` statement can be embedded into: Behavior, Sequence of
  statements or action, Layer,

- The `status` statement embeds statements:

```
### switch
```

```
#### Facets
```

- `value` (any type), (omissible) : an expression

```
#### Definition
```

```
The "switch... match" statement is a powerful replacement for imbricated "if ...
else ..." constructs. All the blocks that match are executed in the order they
are defined. The block prefixed by default is executed only if none have matched
(otherwise it is not).
```

```
#### Usages
```

- The prototypical syntax is as follows:

switch an_expression { match value1 {...} match_one [value1, value2, value3] {...} match_between [value1, value2] {...} default {...} }

* Example:

switch 3 { match 1 {write "Match 1"; } match 2 {write "Match 2"; } match 3 {write "Match 3"; } match_one [4,4,6,3,7] {write "Match one_of"; } match_between [2, 4] {write "Match between"; } default {write "Match Default"; } }

-    See also: [match](#match), [default](#default), [if](#if),

Embedments

-    The `switch` statement is of type: **Sequence of statements or action**

-    The `switch` statement can be embedded into: Behavior, Sequence of
     statements or action, Layer,

-    The `switch` statement embeds statements: [default](#default),
     [match](#match),

tabu

Facets

-    `name` (an identifier), (omissible) : The name of the method. For internal
     use only

-    `aggregation` (a label), takes values in: {min, max}: the agregation method

-    `iter_max` (int): number of iterations

-    `maximize` (float): the value the algorithm tries to maximize

-    `minimize` (float): the value the algorithm tries to minimize

-    `tabu_list_size` (int): size of the tabu list

Definition

This algorithm is an implementation of the Tabu Search algorithm. See the
wikipedia article and [batch161 the batch dedicated page].

Usages

-    As other batch methods, the basic syntax of the tabu statement uses `method
     tabu` instead of the expected `tabu name: id` :

method tabu [facet: value];

* For example:

method tabu iter_max: 50 tabu_list_size: 5 maximize: food_gathered;

Embedments

- The `tabu` statement is of type: **Batch method**

- The `tabu` statement can be embedded into: Experiment,

- The `tabu` statement embeds statements:

task

Facets

- `name` (an identifier), (omissible) : the identifier of the task

- `weight` (float): the priority level of the task

Definition

As reflex, a task is a sequence of statements that can be executed, at each time step, by the agent. If an agent owns several tasks, the scheduler chooses a task to execute based on its current priority weight value.

Usages

Embedments

- The `task` statement is of type: **Behavior**

- The `task` statement can be embedded into: weighted_tasks, sorted_tasks, probabilistic_tasks, Species, Experiment, Model,

- The `task` statement embeds statements:

test

Facets

- `name` (an identifier), (omissible) : identifier of the test

Definition

The test statement allows modeler to define a set of assertions that will be tested. Before the execution of the embedded set of instructions, if a setup is defined in the species, model or experiment, it is executed. In a test, if one assertion fails, the evaluation of other assertions continue.

Usages

- An example of use:

species Tester { // set of attributes that will be used in test setup { // [set of instructions... in particular initializations] } test t1 { // [set of instructions, including asserts] } }

* See also: [setup](#setup), [assert](#assert),

Embedments
* The `test` statement is of type: **Behavior**
* The `test` statement can be embedded into: Species, Experiment, Model,
* The `test` statement embeds statements: [assert](#assert),

[//]: # (keyword|statement_trace)
trace
Facets

Definition

All the statements executed in the trace statement are displayed in the console.

Usages

Embedments
* The `trace` statement is of type: **Sequence of statements or action**
* The `trace` statement can be embedded into: Behavior, Sequence of statements or action, Layer,
* The `trace` statement embeds statements:

[//]: # (keyword|statement_transition)
transition
Facets

  * **`to`** (an identifier): the identifier of the next state
  * `when` (boolean), (omissible) : a condition to be fulfilled to have a transition to another given s

Definition

In an FSM architecture, `transition` specifies the next state of the life cycle. The transition occurs

Usages

* In the following example, the transition is executed when after 2 steps:

state s_init initial: true {   write state;   transition to: s1 when: (cycle > 2) {

-    See also: [enter](#enter), [state](#state), [exit](#exit),

Embedments

-    The `transition` statement is of type: **Sequence of statements or action**

-    The `transition` statement can be embedded into: Sequence of statements or
     action, Behavior,

- The `transition` statement embeds statements:

try

Facets

Definition

Allows the agent to execute a sequence of statements and to catch any runtime
error that might happen in a subsequent `catch` block, either to ignore it (not
a good idea, usually) or to safely stop the model

Usages

- The generic syntax is:

try { statements }

* Optionally, the statements to execute when a runtime error happens in the block can be defined in a fo

try { statements } catch { statements }

Embedments

- The `try` statement is of type: **Sequence of statements or action**

- The `try` statement can be embedded into: Behavior, Sequence of statements
  or action, Layer,

- The `try` statement embeds statements: [catch](#catch),

unconscious_contagion

Facets

- `emotion` (546706): the emotion that will be copied with the contagion

- `name` (an identifier), (omissible) : the identifier of the unconscious
  contagion

- `charisma` (float): The charisma value of the perceived agent (between 0 and
  1)

- `decay` (float): The decay value of the emotion added to the agent

- `receptivity` (float): The receptivity value of the current agent (between 0
  and 1)

- `threshold` (float): The threshold value to make the contagion

- `when` (boolean): A boolean value to get the emotion only with a certain
  condition

Definition

enables to directly copy an emotion presents in the perceived specie.

Usages

-    Other examples of use:

unconscious_contagion emotion:fearConfirmed; unconscious_contagion emotion:fearConfirmed charisma:
0.5 receptivity: 0.5;

Embedments
* The `unconscious_contagion` statement is of type: **Single statement**
* The `unconscious_contagion` statement can be embedded into: Behavior, Sequence of statements or actio
* The `unconscious_contagion` statement embeds statements:

[//]: # (keyword|statement_user_command)
user_command
Facets

  * **`name`** (a label), (omissible) : the identifier of the user_command
  * `action` (26): the identifier of the action to be executed. This action should be accessible in the
  * `category` (a label): a category label, used to group parameters in the interface
  * `color` (rgb): The color of the button to display
  * `continue` (boolean): Whether or not the button, when clicked, should dismiss the user panel it is
  * `when` (boolean): the condition that should be fulfilled (in addition to the user clicking it) in o
  * `with` (map): the map of the parameters::values required by the action

Definition

Anywhere in the global block, in a species or in an (GUI) experiment, user_command statements allows to

Usages

* The general syntax is for example:

user_command kill_myself action: some_action with: [arg1::val1, arg2::val2, …];

-    See also: [user_init](#user_init), [user_panel](#user_panel),
     [user_input](#user_input),

Embedments

-    The `user_command` statement is of type: **Sequence of statements or
     action**

-    The `user_command` statement can be embedded into: user_panel, Species,
     Experiment, Model,

-    The `user_command` statement embeds statements: [user_input](#user_input),

user_init

Facets

-   `name` (an identifier), (omissible) : The name of the panel

-   `initial` (boolean): Whether or not this panel will be the initial one

Definition

Used in the user control architecture, user_init is executed only once when the agent is created. It opens a special panel (if it contains user_commands statements). It is the equivalent to the init block in the basic agent architecture.

Usages

-   See also: [user_command](#user_command), [user_init](#user_init), [user_input](#user_input),

Embedments

-   The `user_init` statement is of type: **Behavior**

-   The `user_init` statement can be embedded into: Species, Experiment, Model,

-   The `user_init` statement embeds statements: [user_panel](#user_panel),

user_input

Facets

-   `returns` (a new identifier): a new local variable containing the value given by the user

-   `name` (a label), (omissible) : the displayed name

-   `among` (list): the set of acceptable values for the variable

-   `init` (any type): the init value

-   `max` (float): the maximum value

-   `min` (float): the minimum value

-   `slider` (boolean): Whether to display a slider or not when applicable

-   `type` (a datatype identifier): the variable type

Definition

It allows to let the user define the value of a variable.

Usages

-    Other examples of use:

user_panel "Advanced Control" { user_input "Location" returns: loc type: point <- {0,0}; create cells
number: 10 with: [location::loc]; }

* See also: [user_command](#user_command), [user_init](#user_init), [user_panel](#user_panel),

Embedments
* The `user_input` statement is of type: **Single statement**
* The `user_input` statement can be embedded into: user_command,
* The `user_input` statement embeds statements:

[//]: # (keyword|statement_user_panel)
user_panel
Facets

  * **`name`** (an identifier), (omissible) : The name of the panel
  * `initial` (boolean): Whether or not this panel will be the initial one

Definition

It is the basic behavior of the user control architecture (it is similar to state for the FSM architectu

Usages

* The general syntax is for example:

user_panel default initial: true { user_input 'Number' returns: number type: int <- 10; ask (number among
list(cells)){ do die; } transition to: "Advanced Control" when: every (10); } user_panel "Advanced Control"
{ user_input "Location" returns: loc type: point <- {0,0}; create cells number: 10 with: [location::loc]; }

-    See also: [user_command](#user_command), [user_init](#user_init),
     [user_input](#user_input),

Embedments

-    The `user_panel` statement is of type: **Behavior**

-    The `user_panel` statement can be embedded into: fsm, user_first, user_last,
     user_init, user_only, Species, Experiment, Model,

-    The `user_panel` statement embeds statements: [user_command](#user_command),

using

Facets

-    `topology` (topology), (omissible) : the topology

Definition

`using` is a statement that allows to set the topology to use by its
sub-statements. They can gather it by asking the scope to provide it.

Usages

-   All the spatial operations are topology-dependent (e.g. neighbors are not
    the same in a continuous and in a grid topology). So `using` statement
    allows modelers to specify the topology in which the spatial operation will
    be computed.

float dist <- 0.0; using topology(grid_ant) { d (self.location distance_to target.location); }

Embedments
* The `using` statement is of type: **Sequence of statements or action**
* The `using` statement can be embedded into: chart, Behavior, Sequence of statements or action, Layer,
* The `using` statement embeds statements:

[//]: # (keyword|statement_Variable_container)
Variable_container
Facets

  * **`name`** (a new identifier), (omissible) : The name of the attribute
  * `category` (a label): Soon to be deprecated. Declare the parameter in an experiment instead
  * `const` (boolean): Indicates whether this attribute can be subsequently modified or not
  * `fill_with` (any type):
  * `function` (any type): Used to specify an expression that will be evaluated each time the attribute
  * `index` (a datatype identifier): The type of the key used to retrieve the contents of this attribute
  * `init` (any type): The initial value of the attribute
  * `of` (a datatype identifier): The type of the contents of this container attribute
  * `on_change` (any type): Provides a block of statements that will be executed whenever the value of
  * `parameter` (a label): Soon to be deprecated. Declare the parameter in an experiment instead
  * `size` (any type in [int, point]):
  * `type` (a datatype identifier): The type of the attribute
  * `update` (any type): An expression that will be evaluated each cycle to compute a new value for the
  * `value` (any type):

Definition

Allows to declare an attribute of a species or an experiment

Usages

Embedments
* The `Variable_container` statement is of type: **Variable (container)**
* The `Variable_container` statement can be embedded into: Species, Experiment, Model,
* The `Variable_container` statement embeds statements:

```
[//]: # (keyword|statement_Variable_number)
```
Variable_number
Facets

  * **`name`** (a new identifier), (omissible) : The name of the attribute
  * `among` (list): A list of constant values among which the attribute can take its value
  * `category` (a label): Soon to be deprecated. Declare the parameter in an experiment instead
  * `const` (boolean): Indicates whether this attribute can be subsequently modified or not
  * `function` (any type in [int, float]): Used to specify an expression that will be evaluated each ti
  * `init` (any type in [int, float]): The initial value of the attribute
  * `max` (any type in [int, float]): The maximum value this attribute can take.
  * `min` (any type in [int, float]): The minimum value this attribute can take
  * `on_change` (any type): Provides a block of statements that will be executed whenever the value of
  * `parameter` (a label): Soon to be deprecated. Declare the parameter in an experiment instead
  * `step` (int): A discrete step (used in conjunction with min and max) that constrains the values this
  * `type` (a datatype identifier): The type of the attribute, either 'int' or 'float'
  * `update` (any type in [int, float]): An expression that will be evaluated each cycle to compute a n
  * `value` (any type in [int, float]):

Definition

Allows to declare an attribute of a species or experiment

Usages

Embedments
* The `Variable_number` statement is of type: **Variable (number)**
* The `Variable_number` statement can be embedded into: Species, Experiment, Model,
* The `Variable_number` statement embeds statements:

```
[//]: # (keyword|statement_Variable_regular)
```
Variable_regular
Facets

  * **`name`** (a new identifier), (omissible) : The name of the attribute
  * `among` (list): A list of constant values among which the attribute can take its value
  * `category` (a label): Soon to be deprecated. Declare the parameter in an experiment instead
  * `const` (boolean): Indicates whether this attribute can be subsequently modified or not
  * `function` (any type): Used to specify an expression that will be evaluated each time the attribute
  * `index` (a datatype identifier): The type of the index used to retrieve elements if the type of the
  * `init` (any type): The initial value of the attribute
  * `of` (a datatype identifier): The type of the elements contained in the type of this attribute if i
  * `on_change` (any type): Provides a block of statements that will be executed whenever the value of
  * `parameter` (a label): Soon to be deprecated. Declare the parameter in an experiment instead
  * `type` (a datatype identifier): The type of this attribute. Can be combined with facets 'of' and 'i
  * `update` (any type): An expression that will be evaluated each cycle to compute a new value for the
  * `value` (any type):

Definition

Allows to declare an attribute of a species or an experiment

Usages

Embedments
* The `Variable_regular` statement is of type: **Variable (regular)**
* The `Variable_regular` statement can be embedded into: Species, Experiment, Model,
* The `Variable_regular` statement embeds statements:

[//]: # (keyword|statement_warn)
warn
Facets

  * **`message`** (string), (omissible) : the message to display as a warning.

Definition

The statement makes the agent output an arbitrary message in the error view as a warning.

Usages

* Emmitting a warning

warn 'This is a warning from' + self;

" '

16.4.2.4 Embedments

- The `warn` statement is of type: **Single statement**

- The `warn` statement can be embedded into: Behavior, Sequence of statements or action, Layer,

- The `warn` statement embeds statements:

16.4.3 write

16.4.3.1 Facets

- `message` (any type), (omissible) : the message to display. Modelers can add some formatting characters to the message (carriage returns, tabs, or Unicode characters), which will be used accordingly in the console.

- `color` (rgb): The color with wich the message will be displayed. Note that different simulations will have different (default) colors to use for this purpose if this facet is not specified

16.4.3.2 Definition

The statement makes the agent output an arbitrary message in the console.

16.4.3.3   Usages

- Outputting a message

```
write 'This is a message from ' + self;
```

16.4.3.4   Embedments

- The `write` statement is of type: **Single statement**
- The `write` statement can be embedded into: Behavior, Sequence of statements or action, Layer,
- The `write` statement embeds statements:
